"The Bank is completely removed from any governmental or political control."

— Gates McGarrah, first president of the Bank for International Settlements, 1931[1]

The world's most exclusive club has eighteen members. They gather every other month on a Sunday evening at 7 p.m. in conference room E in a circular tower block whose tinted windows overlook the central Basel railway station. Their discussion lasts for one hour, perhaps an hour and a half. Some of those present bring a colleague with them, but the aides rarely speak during this most confidential of conclaves. The meeting closes, the aides leave, and those remaining retire for dinner in the dining room on the eighteenth floor, rightly confident that the food and the wine will be superb. The meal, which continues until 11 p.m. or midnight, is where the real work is done. The protocol and hospitality, honed for more than eight decades, are faultless. Anything said at the dining table, it is understood, is not to be repeated elsewhere.

Few, if any, of those enjoying their haute cuisine and *grand cru* wines—some of the best Switzerland can offer—would be recognized by passers-by, but they include a good number of the most powerful people in the world. These men—they are almost all men—are central bankers. They have come to Basel to attend the Economic Consultative Committee (ECC) of the Bank for International Settlements (BIS), which is the bank for central banks. Its current members include Ben Bernanke, the chairman of the US Federal Reserve; Sir Mervyn King, the governor of the Bank of England; Mario Draghi, of the European Central Bank; Zhou Xiaochuan of the Bank of China; and the central bank governors of Germany, France, Italy, Sweden, Canada, India, and Brazil. Jaime Caruana, a former governor of the Bank of Spain, the BIS's general manager, joins them.

In early 2013, when this book went to press, King, who is due to step down as governor of the Bank of England in June 2013, chaired the ECC. The ECC, which used to be known as the G-10 governors' meeting, is the most influential of the BIS's numerous gatherings, open only to a small, select group of central bankers from advanced economies. The ECC makes recommendations on the membership and organization of the three BIS committees that deal with the global financial system, payments systems, and international markets. The committee also prepares proposals for the Global Economy Meeting and guides its agenda.

That meeting starts at 9:30 a.m. on Monday morning, in room B and lasts for three hours. There King presides over the central bank governors of the thirty countries judged the most important to the global economy. In addition to those who were present at the Sunday evening dinner, Monday's meeting will include representatives from, for example, Indonesia, Poland, South Africa, Spain, and Turkey. Governors from fifteen smaller countries, such as Hungary, Israel, and New Zealand are allowed to sit in as observers, but do not usually not speak. Governors from the third tier of member banks, such as Macedonia and Slovakia, are not allowed to attend. Instead they must forage for scraps of information at coffee and meal breaks.

The governors of all sixty BIS member banks then enjoy a buffet lunch in the eighteenth-floor dining room. Designed by Herzog & de Meuron, the Swiss architectural firm which built the "Bird's Nest" Stadium for the Beijing Olympics, the dining room has white walls, a black ceiling and spectacular views over three countries: Switzerland, France, and Germany.[2] At 2 p.m. the central bankers and their aides return to room B for the governors' meeting to discuss matters of interest, until the gathering ends at 5.

King takes a very different approach than his predecessor, Jean-Claude Trichet, the former president

of the European Central Bank, in chairing the Global Economy Meeting. Trichet, according to one former central banker, was notably Gallic in his style: a stickler for protocol who called the central bankers to speak in order of importance, starting with the governors of the Federal Reserve, the Bank of England, and the Bundesbank, and then progressing down the hierarchy. King, in contrast, adopts a more thematic and egalitarian approach: throwing open the meetings for discussion and inviting contributions from all present.

The governors' conclaves have played a crucial role in determining the world's response to the global financial crisis. "The BIS has been a very important meeting point for central bankers during the crisis, and the rationale for its existence has expanded," said King. "We have had to face challenges that we have never seen before. We had to work out what was going on, what instruments do we use when interest rates are close to zero, how do we communicate policy. We discuss this at home with our staff, but it is very valuable for the governors themselves to get together and talk among themselves."

Those discussions, say central bankers, must be confidential. "When you are at the top in the number one post, it can be pretty lonely at times. It is helpful to be able to meet other number ones and say, 'This is my problem, how do you deal with it?'" King continued. "Being able to talk informally and openly about our experiences has been immensely valuable. We are not speaking in a public forum. We can say what we really think and believe, and we can ask questions and benefit from others."[3]

The BIS management works hard to ensure that the atmosphere is friendly and clubbable throughout the weekend, and it seems they succeed. The bank arranges a fleet of limousines to pick up the governors at Zürich airport and bring them to Basel. Separate breakfasts, lunches, and dinners are organized for the governors of national banks who oversee different types and sizes of national economies, so no one feels excluded. "The central bankers were more at home and relaxed with their fellow central bankers than with their own governments," recalled Paul Volcker, the former chairman of the US Federal Reserve, who attended the Basel weekends.[4] The superb quality of the food and wine made for an easy camaraderie, said Peter Akos Bod, a former governor of the National Bank of Hungary. "The main topics of discussion were the quality of the wine and the stupidity of finance ministers. If you had no knowledge of wine you could not join in the conversation."[5]

And the conversation is usually stimulating and enjoyable, say central bankers. The contrast between the Federal Open Markets Committee at the US Federal Reserve, and the Sunday evening G-10 governors' dinners was notable, recalled Laurence Meyer, who served as a member of the Board of Governors of the Federal Reserve from 1996 until 2002. The chairman of the Federal Reserve did not always represent the bank at the Basel meetings, so Meyer occasionally attended. The BIS discussions were always lively, focused and thought provoking. "At FMOC meetings, while I was at the Fed, almost all the Committee members read statements which had been prepared in advance. They very rarely referred to statements by other Committee members and there was almost never an exchange between two members or an ongoing discussion about the outlook or policy options. At BIS dinners people actually talk to each other and the discussions are always stimulating and interactive focused on the serious issues facing the global economy."[6]

All the governors present at the two-day gathering are assured of total confidentiality, discretion, and the highest levels of security. The meetings take place on several floors that are usually used only when the governors are in attendance. The governors are provided with a dedicated office and the necessary support and secretarial staff. The Swiss authorities have no juridisdiction over the BIS premises. Founded by an international treaty, and further protected by the 1987 Headquarters Agreement with the Swiss government, the BIS enjoys similar protections to those granted to the headquarters of the United Nations, the International Monetary Fund (IMF) and diplomatic embassies. The Swiss authorities need the

permission of the BIS management to enter the bank's buildings, which are described as "inviolable."[7]

The BIS has the right to communicate in code and to send and receive correspondence in bags covered by the same protection as embassies, meaning they cannot be opened. The BIS is exempt from Swiss taxes. Its employees do not have to pay income tax on their salaries, which are usually generous, designed to compete with the private sector. The general manager's salary in 2011 was 763,930 Swiss francs, while head of departments were paid 587,640 per annum, plus generous allowances. The bank's extraordinary legal privileges also extend to its staff and directors. Senior managers enjoy a special status, similar to that of diplomats, while carrying out their duties in Switzerland, which means their bags cannot be searched (unless there is evidence of a blatant criminal act), and their papers are inviolable. The central bank governors traveling to Basel for the bimonthly meetings enjoy the same status while in Switzerland. All bank officials are immune under Swiss law, for life, for all the acts carried out during the discharge of their duties. The bank is a popular place to work and not just because of the salaries. Around six hundred staff come from over fifty countries. The atmosphere is multi-national and cosmopolitan, albeit very Swiss, emphasizing the bank's hierarchy. Like many of those working for the UN or the IMF, some of the staff of the BIS, especially senior management, are driven by a sense of mission, that they are working for a higher, even celestial purpose and so are immune from normal considerations of accountability and transparency.

The bank's management has tried to plan for every eventuality so that the Swiss police need never be called. The BIS headquarters has high-tech sprinkler systems with multiple back-ups, in-house medical facilities, and its own bomb shelter in the event of a terrorist attack or armed conflagration. The BIS's assets are not subject to civil claims under Swiss law and can never be seized.

The BIS strictly guards the bankers' secrecy. The minutes, agenda, and actual attendance list of the Global Economy Meeting or the ECC are not released in any form. This is because no official minutes are taken, although the bankers sometimes scribble their own notes. Sometimes there will be a brief press conference or bland statement afterwards but never anything detailed. This tradition of privileged confidentiality reaches back to the bank's foundation.

"The quietness of Basel and its absolutely nonpolitical character provide a perfect setting for those equally quiet and nonpolitical gatherings," wrote one American official in 1935. "The regularity of the meetings and their almost unbroken attendance by practically every member of the Board make them such they rarely attract any but the most meager notice in the press."[8] Forty years on, little had changed. Charles Coombs, a former foreign exchange chief of the New York Federal Reserve, attended governors' meetings from 1960 to 1975. The bankers who were allowed inside the inner sanctum of the governors' meetings trusted each other absolutely, he recalled in his memoirs. "However much money was involved, no agreements were ever signed nor memoranda of understanding ever initialized. The word of each official was sufficient, and there were never any disappointments."[9]

What, then, does this matter to the rest of us? Bankers have been gathering confidentially since money was first invented. Central bankers like to view themselves as the high priests of finance, as technocrats overseeing arcane monetary rituals and a financial liturgy understood only by a small, self-selecting elite.

But the governors who meet in Basel every other month are public servants. Their salaries, airplane tickets, hotel bills, and lucrative pensions when they retire are paid out of the public purse. The national reserves held by central banks are public money, the wealth of nations. The central bankers' discussions at the BIS, the information that they share, the policies that are evaluated, the opinions that are exchanged, and the subsequent decisions that are taken, are profoundly political. Central bankers, whose independence is constitutionally protected, control monetary policy in the developed world. They manage the supply of money to national economies. They set interest rates, thus deciding the value of our savings

and investments. They decide whether to focus on austerity or growth. Their decisions shape our lives.

The BIS's tradition of secrecy reaches back through the decades. During the 1960s, for example, the bank hosted the London Gold Pool. Eight countries pledged to manipulate the gold market to keep the price at around thirty-five dollars per ounce, in line with the provisions of the Bretton Woods Accord that governed the post–World War II international financial system. Although the London Gold Pool no longer exists, its successor is the BIS Markets Committee, which meets every other month on the occasion of the governors' meetings to discuss trends in the financial markets. Officials from twenty-one central banks attend. The committee releases occasional papers, but its agenda and discussions remain secret.

Nowadays the countries represented at the Global Economy Meetings together account for around four-fifths of global gross domestic product (GDP)—most of the produced wealth of the world—according to the BIS's own statistics. Central bankers now "seem more powerful than politicians," wrote *The Economist* newspaper, "holding the destiny of the global economy in their hands."[10] How did this happen? The BIS, the world's most secretive global financial institution, can claim much of the credit. From its first day of existence, the BIS has dedicated itself to furthering the interests of central banks and building the new architecture of transnational finance. In doing so, it has spawned a new class of close-knit global technocrats whose members glide between highly-paid positions at the BIS, the IMF, and central and commercial banks.

The founder of the technocrats' cabal was Per Jacobssen, the Swedish economist who served as the BIS's economic adviser from 1931 to 1956. The bland title belied his power and reach. Enormously influential, well connected, and highly regarded by his peers, Jacobssen wrote the first BIS annual reports, which were—and remain—essential reading throughout the world's treasuries. Jacobssen was an early supporter of European federalism. He argued relentlessly against inflation, excessive government spending, and state intervention in the economy. Jacobssen left the BIS in 1956 to take over the IMF. His legacy still shapes our world. The consequences of his mix of economic liberalism, price obsession, and dismantling of national sovereignty play out nightly in the European news bulletins on our television screens.

The BIS's defenders deny that the organization is secretive. The bank's archives are open and researchers may consult most documents that are more than thirty years old. The BIS archivists are indeed cordial, helpful, and professional. The bank's website includes all its annual reports, which are downloadable, as well as numerous policy papers produced by the bank's highly regarded research department. The BIS publishes detailed accounts of the securities and derivatives markets, and international banking statistics. But these are largely compilations and analyses of information already in the public domain. The details of the bank's own core activities, including much of its banking operations for its customers, central banks, and international organizations, remain secret. The Global Economy Meetings and the other crucial financial gatherings that take place at Basel, such as the Markets Committee, remain closed to outsiders. Private individuals may not hold an account at BIS, unless they work for the bank. The bank's opacity, lack of unaccountability, and ever-increasing influence raises profound questions—not just about monetary policy but transparency, accountability, and how power is exercised in our democracies.

WHEN I EXPLAINED to friends and acquaintances that I was writing a book about the Bank for International Settlements, the usual response was a puzzled look, followed by a question: "The bank for what?" My interlocutors were intelligent people, who follow current affairs. Many had some interest in and understanding of the global economy and financial crisis. Yet only a handful had heard of the BIS. This was strange, as the BIS is the most important bank in the world and predates both the IMF and the

World Bank. For decades it has stood at the center of a global network of money, power, and covert global influence.

The BIS was founded in 1930. It was ostensibly set up as part of the Young Plan to administer German reparations payments for the First World War. The bank's key architects were Montagu Norman, who was the governor of the Bank of England, and Hjalmar Schacht, the president of the Reichsbank who described the BIS as "my" bank. The BIS's founding members were the central banks of Britain, France, Germany, Italy, Belgium, and a consortium of Japanese banks. Shares were also offered to the Federal Reserve, but the United States, suspicious of anything that might infringe on its national sovereignty, refused its allocation. Instead a consortium of commercial banks took up the shares: J. P. Morgan, the First National Bank of New York, and the First National Bank of Chicago.

The real purpose of the BIS was detailed in its statutes: to "promote the cooperation of central banks and to provide additional facilities for international financial operations." It was the culmination of the central bankers' decades-old dream, to have their own bank—powerful, independent, and free from interfering politicians and nosy reporters. Most felicitous of all, the BIS was self-financing and would be in perpetuity. Its clients were its own founders and shareholders—the central banks. During the 1930s, the BIS was the central meeting place for a cabal of central bankers, dominated by Norman and Schacht. This group helped rebuild Germany. The *New York Times* described Schacht, widely acknowledged as the genius behind the resurgent German economy, as "The Iron-Willed Pilot of Nazi Finance."[11] During the war, the BIS became a de-facto arm of the Reichsbank, accepting looted Nazi gold and carrying out foreign exchange deals for Nazi Germany.

The bank's alliance with Berlin was known in Washington, DC, and London. But the need for the BIS to keep functioning, to keep the new channels of transnational finance open, was about the only thing all sides agreed on. Basel was the perfect location, as it is perched on the northern edge of Switzerland and sits almost on the French and German borders. A few miles away, Nazi and Allied soldiers were fighting and dying. None of that mattered at the BIS. Board meetings were suspended, but relations between the BIS staff of the belligerent nations remained cordial, professional, and productive. Nationalities were irrelevant. The overriding loyalty was to international finance. The president, Thomas McKittrick, was an American. Roger Auboin, the general manager, was French. Paul Hechler, the assistant general manager, was a member of the Nazi party and signed his correspondence "Heil Hitler." Rafaelle Pilotti, the secretary general, was Italian. Per Jacobssen, the bank's influential economic adviser, was Swedish. His and Pilotti's deputies were British.

After 1945, five BIS directors, including Hjalmar Schacht, were charged with war crimes. Germany lost the war but won the economic peace, in large part thanks to the BIS. The international stage, contacts, banking networks, and legitimacy the BIS provided, first to the Reichsbank and then to its successor banks, has helped ensure the continuity of immensely powerful financial and economic interests from the Nazi era to the present day.

FOR THE FIRST forty-seven years of its existence, from 1930 to 1977, the BIS was based in a former hotel, near the Basel central railway station. The bank's entrance was tucked away by a chocolate shop, and only a small notice confirmed that the narrow doorway opened into the BIS. The bank's managers believed that those who needed to know where the BIS was would find it, and the rest of the world certainly did not need to know. The inside of the building changed little over the decades, recalled Charles Coombs. The BIS provided the "the spartan accommodations of a former Victorian-style hotel whose single and double bedrooms had been transformed into offices simply by removing the beds and installing desks."[12]

The bank moved into its current headquarters, at 2, Centralbahnplatz, in 1977. It did not go far and now overlooks the Basel central station. Nowadays the BIS's main mission, in its own words, is threefold: "to serve central banks in their pursuit of monetary and financial stability, to foster international cooperation in these areas, and to act as a bank for central banks."[13] The BIS also hosts much of the practical and technical infrastructure that the global network of central banks and their commercial counterparts need to function smoothly. It has two linked trading rooms: at the Basel headquarters and Hong Kong regional office. The BIS buys and sells gold and foreign exchange for its clients. It provides asset management and arranges short-term credit to central banks when needed.

The BIS is a unique institution: an international organization, an extremely profitable bank and a research institute founded, and protected, by international treaties.[14] The BIS is accountable to its customers and shareholders—the central banks—but also guides their operations. The main tasks of a central bank, the BIS argues, are to control the flow of credit and the volume of currency in circulation, which will ensure a stable business climate, and to keep exchange rates within manageable bands to ensure the value of a currency and so smooth international trade and capital movements. This is crucial, especially in a globalized economy, where markets react in microseconds and perceptions of economic stability and value are almost as important as reality itself.

The BIS also helps to supervise commercial banks, although it has no legal powers over them. The Basel Committee on Banking Supervision, based at the BIS, regulates commercial banks' capital and liquidity requirements. It requires banks to have a minimum capital of eight percent of risk-weighted assets when lending, meaning that if a bank has risk-weighted assets of $100 million it must maintain at least $8 million capital.[15] The committee has no powers of enforcement, but it does have enormous moral authority. "This regulation is so powerful that the eight percent principle has been set into national laws," said Peter Akos Bod. "It's like voltage. Voltage has been set at 220. You may decide on ninety-five volts, but it would not work." In theory, sensible housekeeping and mutual cooperation, overseen by the BIS, will keep the global financial system functioning smoothly. In theory.

The reality is that we have moved beyond recession into a deep structural crisis, one fueled by the banks' greed and rapacity, which threatens all of our financial security. Just as in the 1930s, parts of Europe face economic collapse. The Bundesbank and the European Central Bank, two of the most powerful members of the BIS, have driven the mania for austerity that has already forced one European country, Greece, to the edge, aided by the venality and corruption of the country's ruling class. Others may soon follow. The old order is creaking, its political and financial institutions corroding from within. From Oslo to Athens, the far right is resurgent, fed in part by soaring poverty and unemployment. Anger and cynicism are corroding citizens' faith in democracy and the rule of law. Once again, the value of property and assets is vaporizing before their owners' eyes. The European currency is threatened with breakdown, while those with money seek safe haven in Swiss francs or gold. The young, the talented, and the mobile are again fleeing their home countries for new lives abroad. The powerful forces of international capital that brought the BIS into being, and which granted the bank its power and influence, are again triumphant.

The BIS sits at the apex of an international financial system that is falling apart at the seams, but its officials argue that it does not have the power to act as an international financial regulator. Yet the BIS cannot escape its responsibility for the Euro-zone crisis. From the first agreements in the late 1940s on multilateral payments to the establishment of the Europe Central Bank in 1998, the BIS has been at the heart of the European integration project, providing technical expertise and the financial mechanisms for currency harmonization. During the 1950s, it managed the European Payments Union, which internationalized the continent's payment system. The BIS hosted the Governors' Committee of European Economic Community central bankers, set up in 1964, which coordinated trans-European monetary

policy. During the 1970s, the BIS ran the "Snake," the mechanism by which European currencies were held in exchange rate bands. During the 1980s the BIS hosted the Delors Committee, whose report in 1988 laid out the path to European Monetary Union and the adoption of a single currency. The BIS midwifed the European Monetary Institute (EMI), the precursor of the European Central Bank. The EMI's president was Alexandre Lamfalussy, one of the world's most influential economists, known as the "Father of the euro." Before joining the EMI in 1994, Lamfalussy had worked at the BIS for seventeen years, first as economic adviser, then as the bank's general manager.

For a staid, secretive organization, the BIS has proved surprisingly nimble. It survived the first global depression, the end of reparations payments and the gold standard (two of its main reasons for existence), the rise of Nazism, the Second World War, the Bretton Woods Accord, the Cold War, the financial crises of the 1980s and 1990s, the birth of the IMF and World Bank, and the end of Communism. As Malcolm Knight, manager from 2003–2008, noted, "It is encouraging to see that—by remaining small, flexible, and free from political interference—the Bank has, throughout its history, succeeded remarkably well in adapting itself to evolving circumstances."[16]

The bank has made itself a central pillar of the global financial system. As well as the Global Economy Meetings, the BIS hosts four of the most important international committees dealing with global banking: the Basel Committee on Banking Supervision, the Committee on the Global Financial System, the Committee on Payment and Settlement Systems, and the Irving Fisher Committee, which deals with central banking statistics. The bank also hosts three independent organizations: two groups dealing with insurance and the Financial Stability Board (FSB). The FSB, which coordinates national financial authorities and regulatory policies, is already being spoken of as the fourth pillar of the global financial system, after the BIS, the IMF and the commercial banks.

The BIS is now the world's thirtieth-largest holder of gold reserves, with 119 metric tons—more than Qatar, Brazil, or Canada.[17] Membership of the BIS remains a privilege rather than a right. The board of directors is responsible for admitting central banks judged to "make a substantial contribution to international monetary cooperation and to the Bank's activities." China, India, Russia, and Saudi Arabia joined only in 1996. The bank has opened offices in Mexico City and Hong Kong but remains very Eurocentric. Estonia, Latvia, Lithuania, Macedonia, Slovenia, and Slovakia (total population 16.2 million) have been admitted, while Pakistan (population 169 million) has not. Nor has Kazakhstan, which is a powerhouse of Central Asia. In Africa only Algeria and South Africa are members—Nigeria, which has the continent's second-largest economy, has not been admitted. (The BIS's defenders say that it demands high governance standards from new members and when the national banks of countries such as Nigeria and Pakistan reach those standards, they will be considered for membership.)

Considering the BIS's pivotal role in the transnational economy, its low profile is remarkable. Back in 1930 a *New York Times* reporter noted that the culture of secrecy at the BIS was so strong that he was not permitted to look inside the boardroom, even after the directors had left. Little has changed. Journalists are not allowed inside the headquarters while the Global Economy Meeting is underway. BIS officials speak rarely on the record, and reluctantly, to members of the press. The strategy seems to work. The Occupy Wall Street movement, the anti-globalizers, the social network protesters have ignored the BIS. Centralbahnplatz 2, Basel, is quiet and tranquil. There are no demonstrators gathered outside the BIS's headquarters, no protestors camped out in the nearby park, no lively reception committees for the world's central bankers.

As the world's economy lurches from crisis to crisis, financial institutions are scrutinized as never before. Legions of reporters, bloggers, and investigative journalists scour the banks' every move. Yet somehow, apart from brief mentions on the financial pages, the BIS has largely managed to avoid critical

scrutiny. Until now.

PART ONE: **KAPITAL ÜBER ALLES**

"I rather hope that next summer we may be able to inaugurate a private and eclectic Central Banks 'Club', small at first, large in the future."

— Montagu Norman, governor of the Bank of England, to Benjamin Strong, governor of the Federal Reserve Bank of New York, in 1925[1]

One day in the summer of 1929, Montagu Norman, the governor of the Bank of England, picked up the telephone and spoke to Walter Layton, the editor of *The Economist*. Norman excitedly asked Layton to come to his office as soon as possible to discuss a very important matter.

During Norman's term as governor, from 1920 to 1944, he was one of the most influential men in the world, an apparently permanent bastion of the global financial system. His gnomic utterances were scoured for meaning. When he was re-appointed governor in 1932, the *New York Times* described him as overseeing Britain's "invisible empire of wealth." "Gold standards may come and go," the article noted, "but Montagu Norman remains."[2] Such was Norman's power that a single speech could move markets. When, in October 1932, Norman gloomily proclaimed at a bankers' dinner in London that the world's economic disorder was beyond the control of any man, government, or country, stocks, bonds, and the dollar all slid sharply and quickly in New York.

Layton was not surprised by Norman's agitated manner. The governor was a scion of an old and respected banking dynasty, but his mental state was an open secret among financial insiders. Norman was a mercurial figure, a manic-depressive, and a workaholic, notorious among financial insiders for his mood swings. Shy and hypersensitive, Norman was introverted to the point of neurosis. Before the First World War, Norman had consulted Carl Jung, the Swiss founder of analytical psychology, to discuss a course of treatment, with no success. Jung had implied that Norman was untreatable, which did not help matters.

The world's most powerful banker abhorred publicity, being recognized or socializing, and was prone to fainting fits. He once threw an inkpot at the head of an underling who failed to meet his exacting standards. "He was a very unlikely banker. He was more like a seventeenth-century nobleman or painter," recalled his stepson, Peregrine Worsthorne. "He was always very neurotic and had very bad nervous breakdowns. He was very shy and a loner. He had no care for conventions. He came down to dinner without socks and traveled to work on the underground, which was very unusual in those days."[3]

Nor did Norman look the part of a sober financier, with his cape, neatly trimmed Van Dyke beard, and sparkling, jeweled tiepin. But despite his own flamboyant dress sense, he disapproved of showy behavior, said Worsthorne. "He lived very austerely and discouraged all signs of ostentation. He hated cocktail parties." Norman's horror of publicity naturally had precisely the opposite effect. Although when he sailed across the Atlantic he used an assumed name because the press covered his every move, hordes of journalists and photographers still awaited when he disembarked in New York.

The balmy months in 1929 were the last hurrah of the Roaring Twenties. The American bull market was still growing. Share prices kept rising. The value of stock in Radio Corporation of America (RCA) rose by almost 50 percent in a single month. Even Wall Street's shoeshine boys were passing on tips to their broker customers. In August a brokerage firm announced a new service for those heading to Europe on ocean liners: on-board trading during the weeklong crossing.

Layton, responding to Norman's summons, quickly made his way to the bank's headquarters at Threadneedle Street, the epicenter of the city, as London's financial quarter is known. Surrounded by a high wall, covering most of a city block, the bank's headquarters were meant to impress, even to intimidate. Behind the giant bronze door lay a complex of courtyards, banking halls, and a garden with a fountain, a veritable Alhambra of money, crowded with clerks and underlings who were bustling along its corridors. Even the terminology was regal: the bank was ruled over not by a board, but by a "court."

Layton was ushered into Norman's office where he sat at a mahogany table in the center of the wood-paneled room. Norman wanted to talk about a new bank, to be called the Bank for International Settlements. The BIS was being set up in connection with the Young Plan, the latest and hopefully final program for implementing German reparations payments for the First World War. But Norman had much more ambitious ideas. The BIS would be the world's first international financial institution. It would be a meeting place for central bankers. Away from the demands of politicians and the prying eyes of nosy journalists, the bankers would bring some much needed order and coordination to the world financial system. But for the BIS to succeed and properly fulfill its potential, Norman explained, he needed Layton's help. A subcommittee would soon meet in Baden-Baden, in Germany, to draw up the bank's statutes. The editor of *The Economist*, Norman said, was just the man to draft the BIS's constitution, one that must, above all, guarantee the bank's independence from politicians.

TO UNDERSTAND HOW and why the BIS wields such influence today, it is necessary to step back to the early 1920s and the arguments about German reparations payments for the First World War. German war guilt was enshrined in the 1919 Treaty of Versailles. But no amount of money could bring back the dead, whose numbers were almost incomprehensible. In July 1916, on the first day of the Battle of the Somme, Britain lost 60,000 men—the equivalent of a medium-sized town, mown down in a few hours. France lost a total of 1.4 million soldiers during the four years of fighting, and Germany lost 2 million. The United States, which did not enter the conflict until 1917, lost 117,000 men.

Reaching agreement on German reparations was a slow, complicated, and politically fraught task. The First World War had internationalized conflict to an unprecedented degree. Its financial fallout was similarly globalized. The war had exacted a terrible cost on Europe's economies, as well as its populations. The fledgling international financial system was ill-designed to deal with the complex demands that were now being placed on it. Where would Germany find the money to pay? What would be the mechanisms by which it would do so? Who would oversee and regulate the reparations payments? These arcane discussions shaped the role, structure, and privileged legal status of the BIS.

In 1919—just as there would be in 1945—there were, broadly, two schools of thought: the punishers and the rebuilders. France led the punishers. "Les Boches," said the French, must, and will, pay for their crimes, many of which were carried out on French soil. Norman and the rebuilders, who included most of Wall Street, believed otherwise. Europe could be reconstructed, but its future lay in trade and financial cooperation. The aim was not to reduce Germany to penury, but to help it fix its economy and start trading again as soon as possible.

In April 1921 the Reparations Commission announced that Germany would pay a total of 132 billion gold marks ($31.5 billion), payable at 2 billion marks a year. The commission might as well have demanded ten times as much. Germany was still reeling from its defeat, society was collapsing, unemployment soared, and there were severe shortages of food. Right-wing extremists—the Freikorps—battled Marxist militants in the streets. Workers' councils took control of Hamburg, Bremen, Leipzig, and central Berlin. This was not the salon Marxism of Greenwich Village or San Francisco, but the real thing—raw and bloody. Hostages were taken, factories were seized, and prisoners were lined up against walls

and shot.

Karl Marx's predictions about the inevitable destruction of capitalism seemed to be becoming truer by the hour—especially in his homeland. The bankers' fears that Germany was about to follow Russia into Communism seemed entirely justified. Hyperinflation set in as the government printed money to keep the economy functioning. Shoppers used wheelbarrows to move the bundles of notes needed to buy basic staples. The chaos had to be stopped. On November 13, 1923, five days after Adolf Hitler's failed Beer Hall Putsch in Munich, a tall, imperious German started work as Reich currency commissioner. Hjalmar Schacht demanded, and got, near-dictatorial powers. Working out of a former janitor's closet, he set to work on stabilizing the value of Germany's new currency, the rentenmark. Currencies were usually backed by gold, but the rentenmark was backed by the value of Germany's land and holdings since there was no gold available to back the new currency. This was a somewhat hazy idea—how could the bearer of a rentenmark redeem his money? Would he be given a small piece of a field?

This concern did not matter. As long as Schacht was in office, nobody would want to redeem a rentenmark. He brilliantly understood the key point of the psychology of money, which is as valid today as it was in the hyperinflation of the 1920s: *the appearance of financial stability creates monetary value*. If people believed that someone was in charge, that the chaos would end, and that the rentenmark had value, then it would be valued. The first notes were printed on November 15, 1923. One rentenmark could be exchanged for one trillion old marks (1,000,000,000,000). One U.S. dollar cost 4.2 rentenmarks, a return to the pre-WWI exchange rate. The aim, Schacht said, was to "make German money scarce and valuable." Other than the logistics of printing and distributing the bank notes and convincing Schacht's foreign colleagues that order had been returned to the German economy, there was not that much more to it.

When German reporters asked Clara Steffeck, Schacht's secretary, what he did all day, she replied,

> *What did he do? He sat in his dark room, which smelled of old cleaning rags, and he smoked. Did he read letters? No. And he dictated no letters. But he phoned a lot all over the world, about domestic and foreign currency. Then he smoked some more. We didn't eat much. He usually left late and took public transportation to go home. That was all.*[4]

Not quite "all." Taxes were raised, and four hundred thousand German public employees were sacked. But the rentenmark successfully stopped the German inflation so well that on December 22, 1923, Schacht was promoted to be president of the Reichsbank, while retaining his position as currency commissioner. He could now attend cabinet meetings. "Within a few weeks," notes John Weitz, Schacht's biographer, "he had virtually become Germany's economic dictator."[5]

Schacht certainly looked the part of a strict Prussian banker: his hair was parted precisely down the middle, and his moustache flared briefly under his nose before stopping at a determined mouth. His eyes stared out suspiciously through a pair of pince-nez. He walked with a rigid, almost military manner and wore shirts with high celluloid collars. In fact he was not Prussian at all but was born in North Schleswig, in a land perennially shunted back and forth between Germany and Denmark. Whoever ruled the province, its inhabitants were a stubborn, hardy people. They adapted easily to their alternating masters but retained their tenacity and independence—qualities that would serve Schacht well. His grandfather, Wilhelm, was a country doctor who raised twelve children and charged every patient, rich or poor, sixty Pfennigs. Schacht's father, also called Wilhelm, was a schoolteacher who immigrated to the United States. He worked in a German brewery in Brooklyn and became a naturalized citizen. Hjalmar's mother was a feisty noblewoman, Baroness Constanze von Eggers.

The Schachts settled in New York City, but they did not prosper, and Wilhelm brought his family back to Europe. In 1876 they moved to Tinglev, now in Denmark, and the following year their second son was born. At first they wanted to name him in honor of Horace Greeley, an influential New York journalist and politician who campaigned against the slave trade. The baroness was proud of her radical views—her father had worked to abolish serfdom in Denmark. The infant's grandmother argued that the boy should at least have a proper Danish name first, so the family compromised on Hjalmar Horace Greeley Schacht.

The family was constantly on the move. They lived for a while in Hamburg and then relocated to Berlin. Hjalmar proved to be a diligent student. He enrolled at Kiel University and studied political economy. He worked as a journalist, tried public relations, and then joined the Dresdner Bank. His diligence, attention to detail, and austere manner helped ensure he was soon noticed. Schacht traveled to the United States with other bank officials. They met President Franklin Roosevelt and were invited to lunch in the partners' dining room at J. P. Morgan. Schacht's understanding of the world outside Germany, and his fluent English, proved invaluable. He was promoted to be deputy director of Dresdner Bank and joined the board of the Reichsbank.

So in 1923, with the rentenmark established, the next step was to build a gold reserve to give the new currency real backing. This is why, on the evening of December 31, the Reichsbank president stepped off the train at Liverpool Street station in central London. To Schacht's surprise and delight, he was met on the platform by Montagu Norman himself. "I do hope we shall become friends," said Norman, with a shy smile. Schacht told Norman that he wanted the Bank of England to lend $25 million to a new subsidiary of the Reichsbank, the Gold Discount Bank. The new bank would instantly alter global perceptions of the country's financial prospects. The imprimatur of the governor of the Bank of England would open doors throughout Wall Street and the City of London.

Tenacious as ever, Schacht got his money.

SCHACHT HAD SWEET-TALKED Norman, but the reparations question remained unresolved. America was tired of squabbling Europeans who could not get their houses in order and also recognized that there could be no lasting prosperity while Europe lurched from one financial crisis to another. A new reparations committee was set up under the chairmanship of Charles Dawes, an irascible American banker. The Dawes Committee met in Paris in January 1924. Owen D. Young, the president and chairman of the General Electric Company and the RCA, accompanied Dawes. Young was a consummate diplomat and needed to be. His job was to persuade France to ease the terms of the reparations schedule, which was destroying the German economy, and thus preventing a European recovery, and then to persuade Germany to accept much more stringent external control of its finances.

The Dawes Committee issued its recommendations on April 9. Germany's payments would be reduced for a while, and would increase later, after the economy had stabilized. That stabilization would be based in part on a loan of 800 million gold marks, to be floated on the international market. The German government would hold the funds in marks, which would then paid into an escrow account at the Reichsbank. This account would be controlled by a foreign official known as the agent-general, who could decide how the monies would be used and when they would be released—so as not to flood the markets and affect the value of the Reichsmark. The Reichsbank was placed under the control of a fourteen-man board of seven foreigners and seven Germans.

American companies rushed to invest in Germany. The Great War had triggered an economic boom in the United States. Unlike Europe, mainland America had been spared war damage. Its factories and farms and its mines and industrial plants were all untouched and operating at full capacity. The Dawes Plan loan

was floated in New York and London in October and was quickly oversubscribed. American banks soon clamored to finance the companies now investing in the Germany economy.

Between 1924 and 1928, Germany borrowed $600 million a year, half of which was provided by American banks. Much of it swiftly returned from whence it had come. Like modern bailouts, the money swirled back and forth, raising and lowering balance sheets, boosting confidence and keeping the markets happy. As John Maynard Keynes wrote, "The United States lends money to Germany, Germany transfers its equivalent to the Allies, the Allies pay it back to the United States Government. Nothing real passes—no one is a penny the worse. The engravers' dies, the printers' forms are busier. But no one eats less, no one works more."[6] Some, like Schacht, believed that no one was a penny the better—and he was right. The vast sums were merely a financial adhesive strip. And in October 1929, when Wall Street crashed, American investors frantically pulled out of their German investments in droves.

Once again, Germany faced economic disaster. But if Weimar Germany defaulted, the global economy might crash. It was clear that the reparations issue had to be settled. Even Seymour Parker Gilbert, the agent-general in charge of implementing the Dawes Plan, argued that the country needed to take control of its financial destiny. Gilbert was not popular. In 1928 German nationalists staged his mock coronation. Ten thousand people watched his effigy crowned "the new German Kaiser who rules with a top hat for a crown and a coupon clipper for scepter."[7]

The answer to the never-ending German reparations question was, of course, another conference. This one was named after its chairman, Owen Young. The delegations arrived in Paris in February 1929 in the coldest winter for nearly a century. The gap between France and Germany over Germany's reparations bill was as cavernous as ever. Schacht made his opening offer: $250 million a year for the next thirty-seven years. Emil Moreau, the equally stubborn governor of the Bank of France, demanded $600 million a year for sixty-two years. Perhaps even that might not be enough, he informed Young. France might yet settle for nothing less than $1 billion.

Moreau refused to budge, and so did Schacht. Any initial optimism soon soured. The Germans were unnerved by the French secret police, who were tapping the German telephones. Schacht and his colleagues communicated with Berlin in coded telegrams. He traveled back every fortnight to consult with the government. Lord Revelstoke, the second in command of the British delegation, wrote in his diary that Schacht had resumed "his most negative attitude" was "unhelpful to the last degree." With his "hatchet, Teuton face and burly neck and badly fitting collar," he resembled "a sea-lion at the zoo."[8]

Whatever sum was finally agreed upon, there was at least some consensus that a new bank would be needed to manage Germany's reparations. Schacht and Norman argued that the new bank would keep the issue free of politics and manage it on a purely financial basis. This was unlikely, as there were no more politically charged issues than reparations, but it showed how the two governors both saw the benefit of a bank free of political constraints. Years later, Schacht titled his autobiography *The Old Wizard*. He certainly cast his spell over Owen Young. Germany was paying its reparations by borrowing from other countries, Schacht explained to the conference chairman. Such a system was no longer feasible. If the Allies really wanted Germany to be able to pay its obligations, the country needed to become productive again. Instead of lending to Germany, the Allies should lend to underdeveloped countries so they could buy their industrial equipment from Germany.

Young asked how such a plan could be put into practice. Schacht had a ready answer: by setting up a bank. "A bank of this kind," argued Schacht, "will demand financial cooperation between vanquished and victors that will lead to community of interests, which in turn will give rise to mutual confidence and understanding and thus promote and ensure peace." Schacht recalled the setting in his memoirs:

Owen Young, seated in his armchair, puffing away at his pipe, his legs outstretched, his great keen eyes fixed unswervingly on me. As is my habit when propounding such arguments, I was doing a quiet and steady "quarter deck" up and down the room. When I had finished there was a brief pause. Then his whole face lighted up and his resolve found utterance in words: "Dr. Schacht, you gave me a wonderful idea and I am going to sell it to the world."[9]

The Allies then presented their proposal: Germany would pay $525 million a year for thirty-seven years and $400 million a year for the following twenty-one years.

Schacht would have none of it. He proclaimed that to meet these terms Germany must take possession again of all its former colonies, most of which were in Africa. He also demanded the return of the Danzig corridor, which linked Poland to the Baltic Sea, which would tear up the postwar peace treaty. When Moreau heard this he slammed the table with his fist and hurled his ink blotter across the room. A cartoon in a French newspaper summed up the local mood. It showed Moreau asking Schacht, "All right, Excellency, how much do we owe you?"

On April 19, 1929, Lord Revelstoke suddenly died. The Young Conference was adjourned. All sides finally reached agreement on June 7. Germany would pay almost $29 billion, over fifty-eight years. Control of German economic policy was returned to Berlin. A new bank would administer the payments. Schacht wrote of its birth: "In the meantime my idea of a Bank for International Settlements had met with such enthusiastic response from all those taking part in the Young Conference that soon there was not one among them who would not have liked to claim the suggestion as his own."[10] As the delegates signed the final version, the curtains in the meeting hall caught fire.

The Young Plan was accepted in principle at the First Hague Conference, and seven committees were set up to work out the technical details. At Schacht's suggestion, the seventh, the Organization Committee, gathered in Baden-Baden. This was the most important committee, and it was responsible for drafting the statutes of the new bank and its relations with the host country, which would regulate its legal status. The delegates argued about governance, the role of the directors and managers, and even the official language of the new bank's statutes. It was eventually agreed that both the French and English texts would be authentic. The bank would hold central banks' gold and convertible currency deposits. These deposits could be used to settle international payments without having to either physically move the gold between banks or trade the currency through foreign exchange markets. The BIS would be an international clearinghouse for central banks, the world's first. And with the broad outline settled, the next question was where the new bank should be located. Montagu Norman and the British government pushed for London. France objected, on principle, and argued that the new bank should be located in a small country. There was some talk of Amsterdam, and finally the delegates settled on Basel, Switzerland, which was conveniently located on several international railway lines and on the borders of France and Germany.

MEANWHILE IN LONDON, Walter Layton, the editor of *The Economist*, was still grappling with the new bank's constitution. The key point, as Layton recalled, was to "work out some form of words that would place the bank beyond the reach of governments." Layton "struggled hopelessly" and then told Norman that he had failed.

"Why do you insist it can't be done?" Norman demanded, annoyed.

"Because it's the right of every democratic government to reserve its freedom of action," Layton replied—an argument that would resonate through the decades.[11] Layton admitted defeat. The constitution was eventually drafted by one of the many committees set up to establish the BIS. But Norman was

victorious: the bank's statutes, still extant today, enshrined its absolute independence from interfering politicians and governments. As for Schacht, chastened and unhappy about the reparations demands of the Young Plan, he traveled to the spa of Marienbad, in Czechoslovakia, to spend time with his wife, Luise. Narrowminded, rigid, and intensely Prussian (as he later described her), Luise met him at the train station. She shouted, "You should never have signed."

But Schacht, and Montagu Norman, had their bank.

> *"The hangover of secrecy was, indeed, so strong that the attendants would not permit a look into that sacred room even after all the directors had left."*
>
> — Clarence K. Streit, on the BIS boardroom after the directors' meeting, writing in the *New York Times Magazine*, July 1930

In September 1930, a few months after the BIS opened for business, an American lawyer named Allen Dulles sat down in his office at 37 Rue Cambon, in Paris, to write a letter to Leon Fraser. Fraser, a fellow American, was also a lawyer. A former reporter for the *New York World* newspaper, Fraser had served as general counsel for the execution of the Dawes Plan and had taken part in the negotiations at Baden-Baden on the structure of the BIS. Fraser was now a board member of the BIS and the bank's alternating president.

Dulles was confident that his request, which was simple enough, would be granted. After all, he was a scion of one of the most powerful families in the United States. His uncle, Robert Lansing, had served as secretary of state, as had his grandfather, John W. Foster. Born in 1893, in Watertown, New York, Dulles had graduated from Princeton University and joined the US Foreign Service. He was posted to Vienna, Austria, until the United States entered the war in 1917, when he moved to Bern, Switzerland, to work as a junior intelligence officer at the US Legation. Neutral Switzerland, home to squabbling émigrés, businessmen, and revolutionaries, provided a bountiful harvest of information. "It is almost impossible to stop for any length of time in Switzerland," Dulles wrote, "without coming into contact with questionable characters. Bern is just full of agents and representatives of all nationalities."[1]

Dulles relished the world of shadows. Even as a precocious schoolboy, he had shown an insatiable appetite for intrigue and geopolitics. He wrote his first book at the age of seven. *The Boer War* was short treatise on how the Boers, the Dutch settlers, had first claim on southern Africa, as they had arrived there before their British overlords. (Montagu Norman, who fought in the Second Boer War, at the start of the twentieth century, might have disagreed.) Seven hundred copies were privately printed and sold at fifty cents each, with the proceeds being donated to a Boer charity.

But the future director of the CIA did not always know how to assess a potential source. He later loved to recount the story of how one day in April 1917 the telephone rang at the US Legation in Bern. Dulles took the call. A Russian émigré leader urgently wanted to meet with an American diplomat. Dulles refused, as he wanted to play tennis instead. The next day the man who had telephoned left Switzerland on a sealed train for the Finland Station—a railway station in St. Petersburg, Russia. The city would later be renamed Leningrad in his honor. From Bern, Dulles was dispatched to Paris, as part of the US team at the 1919 Paris Peace Conference. Officially, he was included as a member of the commission drawing up the boundary of the new state of Czechoslovakia. In fact, Dulles was running the American diplomatic intelligence operation for central Europe and courting and monitoring its émigrés, exiles, and revolutionaries.

By 1930, when Dulles wrote to Leon Fraser, Dulles had left the Foreign Service. He and his brother, John Foster Dulles, became partners at Sullivan & Cromwell—the most powerful law firm in the United States, if not the world—headquartered at 48 Wall Street, in New York. Allen Dulles ran Sullivan & Cromwell's office in Paris and knew Hjalmar Schacht well. In Paris in 1919, Dulles had learned about

diplomacy. And in Paris in 1930, he would learn about the world of high finance and the BIS. Dulles, wrote biographer Peter Grose, was "plunged into a realm where sovereign frontiers were transparent and the trappings of democracies seldom allowed to penetrate. Like beguiled readers of Eric Ambler or Graham Greene, Allen discovered that only a thin line divided respectable high finance from a shadowy underworld."[2]

While Montagu Norman and Hjalmar Schacht had exploited the chaos around the German reparations question to finesse the world's leading powers into creating the BIS, the Dulles brothers used Europe's disorder to broker deals and monetary instruments to refinance Germany that were so complex that few outside their offices at Sullivan & Cromwell could understand them.

Much of this web was connected to the BIS, via the Dulles brothers and their friends on Wall Street and in London and Germany. New York banks had led the way during the 1920s in raising money for Germany, and the City of London had also provided significant funds. Foremost among the British banks was J. Henry Schröder, the London operation of the well-established German banking firm of the same name that was based in Hamburg. Schröder, in London, set up a trust to invest in numerous German firms, including IG Farben, Siemens, and Deutsche Bank. Frank Tiarks, who was a partner in the London branch of Schröder, set up a subsidiary in New York, called Schrobanco. It opened for business in October 1923 and was an instant success. The president of Schrobanco was an American banker named Prentiss Gray, who was a close friend of John Foster Dulles's, whom Gray had met at the Paris Peace Conference. Schröder's historic German connections and contacts made that country a natural focus of Schrobanco's. The company quickly became one of the leading agents for doing business in Germany and later, for processing loans under the Dawes and Young reparations plans. Among Schrobanco's shareholders were a number of German, Swiss, and Austrian private banks, which included, naturally, the Hamburg branch of J. Henry Schröder, as well as a bank called J. H. Stein of Cologne. One of J. H. Stein's partners, who was a scion of the Schröder dynasty, would later join the board of the BIS and use J. H. Stein to funnel money from German industrialists to Heinrich Himmler's personal slush fund.

Frank Tiarks was a director of the Bank of England and a close colleague of Montagu Norman. Tiarks had his eye on an American financier named Gates McGarrah, whom Tiarks wanted to recruit to the board of Schrobanco. McGarrah, whom Tiarks described as "one of the most important American bankers," was a director of the Federal Reserve Bank of New York. He also had excellent connections in Germany—he had represented the United States at the Reichsbank when it was held under international control. McGarrah stayed on the Schrobanco board until 1927 when he returned to the Federal Reserve Bank of New York as chairman. He stayed there until 1930—when he was appointed the first president of the BIS. As for Schrobanco, its complicated German investments were in good hands: the bank's lawyer was Allen Dulles. The links were so close that in 1929 Schrobanco moved into spacious new offices at 48 Wall Street—the same building that housed Sullivan & Cromwell.

ALLEN DULLES HAD a simple request for Leon Fraser that autumn of 1930. His sister, Eleanor Lansing Dulles, had received a scholarship from Harvard University to write a book about the BIS. Eleanor Dulles was a well-regarded academic and currency expert, who had previously written a book about the French franc. Allen Dulles wrote, "Anything you can do for her would be greatly appreciated, and I can assure you she is a very discreet person."[3] Like her brothers, Eleanor Dulles also had easy access to the world's most powerful bankers and financiers.

Allen Dulles's letter was not the first Fraser had received that asked him to assist Eleanor. Owen Young had written in May of that year. And Gates McGarrah, the BIS president, was also getting letters about Eleanor Dulles. Paul Warburg, the eminent banker, had written to McGarrah from the headquarters

of M. M. Warburg at 40 Wall Street, in New York. Warburg explained that Eleanor was a "sister of my good friend John Foster Dulles, whose name is well known to you as a writer on international questions and whom you undoubtedly know personally."[4]

Jackson Reynolds, president of the First National Bank of New York, who had chaired the BIS Organization Committee in Baden-Baden, wrote to McGarrah from 2 Wall Street. He asked McGarrah to assist Miss Dulles—especially as she was the sister of Reynolds' friend, John Foster Dulles.

There were few, if any, people in the United States then with a more powerful and influential set of friends than John Foster Dulles, who served as legal counsel to the US delegation at the Paris Peace Conference, where he had specialized in German war reparations. His time in Paris gave him a privileged insight into the workings of international finance and diplomacy and a network of coveted contacts. Dulles's client list during the 1920s read like a who's who of American finance: J. P. Morgan; Kuhn, Loeb & Co.; Harris, Forbes & Co.; Brown Brothers; W. A. Harriman; and Goldman Sachs. Dulles arranged tens of millions of dollars' worth of loans to clients, including to the cities of Munich, Frankfurt, Nuremberg, Berlin, and Hanover, and to the Union of German Mortgage Banks, the Berlin City Electric Company, Hamburg Street Railways, and the State of Prussia. Dulles also worked on the Dawes Plan German Loan in 1924 and the German Government International Loan of 1930 that had been instigated by the Young Committee.[5]

Wall Street in the 1920s was possessed by a near-mania to lend to Germany. In 1923 American banks and finance houses sent abroad $458 million in long-term capital. By 1928 that sum had risen to $1.6 billion. The German credit bubble reached ludicrous extremes. A small village in Bavaria, which needed around $125,000, was persuaded to borrow $3 million.[6] But the real significance of this flow of capital was not just financial. The bonds between the American bankers, businessmen, and industrialists, and their German counterparts, would prove far more durable than the doomed Weimar Republic, and even the Third Reich. With the BIS as the central point of contact, these links would endure during the Second World War and reshape Europe after 1945.

Allen Dulles returned to Bern during the Second World War, as a far more experienced, powerful, and influential spymaster, harvesting much information through his assets at the BIS. John Foster Dulles went on to become US Secretary of State for the Eisenhower administration during the 1950s at the height of the Cold War. The Dulles brothers would help ensure that Nazi bankers, businessmen, and industrialists—many of whom should have been tried for war crimes—were seamlessly integrated back into powerful positions in the new Federal Republic of Germany.

FOR HJALMAR SCHACHT and Montagu Norman, January 20, 1930, was a date to savor: they had created a bank beyond the reach of either national or international law. On that date the governments of the United Kingdom, France, Germany, Belgium, Italy, Japan, and Switzerland signed an extraordinary document. The Hague Convention guaranteed that the BIS would be the world's most privileged and legally protected bank. Its statutes, which remain in force to this day, essentially make the BIS untouchable. Article 10 of the BIS Constituent Charter noted,

> *The Bank, its property and assets and all deposits and other funds entrusted to it shall be immune in time of peace and in time of war from any measure such as expropriation, requisition, seizure, confiscation, prohibition or restriction of gold or currency export or import, and any other similar measures.*

The BIS enjoys the legal privileges of an international organization, but, arguably, it is not one as usually understood by the term. It is a highly profitable bank that is accountable to, and controlled by, its members: central banks. Under the cover of the Young Plan, as well as the need for an impartial financial institution to administer German reparation payments, Norman, Schacht, and the central bankers had by brilliant sleight of hand created a bank with unprecedented powers and privileges. As Gianni Toniolo, the official historian of the BIS, notes,

> *It was no accident that, although the settlement of the reparations problems had been the immediate cause for setting up the BIS, the bank's statutes defined its actual purpose much more broadly:*
>
> *To promote the co-operation of central banks and to provide additional facilities for international financial operations; and to act as trustee or agent in regard to international financial settlements entrusted to it under agreements with the parties concerned.*[7]

In February 1930, the governors of the central banks of Britain, France, Italy, Germany, and Belgium gathered with representatives from Japan and three American banks to sign the BIS's instrument of foundation. As the Federal Reserve Bank of New York was not permitted to own shares, for political reasons, a consortium was formed—J. P. Morgan, the First National Bank of New York, and the First National Bank of Chicago—to represent the United States. The BIS formally came into existence on February 27, 1930. The bank's initial share capital was set at 500 million Swiss francs, which was divided into 200,000 shares of 2,500 gold francs. The governors of the founding central banks were ex officio members of the board of directors. Each could appoint a second director of the same nationality. The second director did not have be a central banker. He could be drawn from finance, industry, or commerce—a provision that would later prove crucial in ensuring Nazi influence over the BIS.

The BIS was incorporated under Swiss law. Its authorized activities included the following:

- buying, selling and holding gold for its own account or for central banks
- buying and selling securities other than shares
- accepting deposits from central banks
- opening and maintaining deposit accounts with central banks
- acting as an agent of or correspondent for central banks
- entering agreements to act as a trustee or agent in connection with international settlements

There were some restrictions that were intended to prevent the BIS from becoming a competitor of commercial banks. The bank could not issue banknotes, open accounts for individuals or commercial organizations, own property other than its headquarters or offices, or have a controlling interest in a business. (The immunities granted under international treaty for reparations settlements did not apply to all of its banking operations to ensure that it maintained the confidence of the international markets.)

Even better, although the BIS was protected by international treaty, unlike the League of Nations, it was not dependent on budgetary contributions from its members. It enjoyed a guaranteed revenue stream from the reparations payments that it would manage under the Young Plan, as well as from the highly profitable services it would carry out for its clients, the central banks. In the final analysis, notes Toniolo, the BIS, "although founded by an international treaty sanctioned by national governments, was very much tailored to the views and requirements of the national banks."[8] The key provisions of the bank's statutes

were given "protected" status and so could only be changed with the consent of all signatories to the Hague Convention.

The BIS was quickly inundated with job applications, even though it was located in humdrum Basel. Its comparatively modest headquarters at the Grand Hôtel et Savoy Hôtel Univers, next door to Basel main railway station at least offered convenient direct connections to Paris, Vienna, Milan, and Geneva. An article in the *New York Times Magazine*, headlined "The Cashless Bank that Deals in Millions," reported,

> *There is only one bank in Basel that does not look like a million dollars. It is the super-bank. Indeed, it is doubtful if there is anywhere a bank that looks less like a bank than does the Bank for International Settlements. . . . There is no "Bank for International Settlements" stretching in big solid letters across its façade. There is no ostentatiously small bronze plaque at the door. There is nothing at all to reveal its identity to the passer-by.*[9]

Nor did the building sound like a bank. There were no counters where banknotes rustled, no adding machines, nor even the sound of a pen scratching on a ledger. The monies did not physically move through the BIS. When Germany made a reparations payment, it informed the BIS that the Reichsbank had credited the BIS's account in Berlin. The BIS then informed the national banks of those countries receiving reparations, such as, for example, Britain, that the monies were available to draw on, if they so wished. If they did not, in case the movement of substantial sums might affect exchange rates, the funds remained in the BIS's account. In the meantime, the BIS used the funds earmarked for Britain to buy securities—which it could sell if and when Britain wanted to draw its monies.

That was the theory. The practice, at least at first, was not quite so smooth. In February 1931, Gates McGarrah, the bank's American president, wrote to H. C. F. Finlayson, in Athens, asking about the Bank of Greece's gold. Finlayson, a former British financial attaché in Berlin, was now an adviser to the Bank of Greece. Some of the Greek bank's gold may have gone missing. Rather like nowadays, it seemed the accounting at the Bank of Greece left something to be desired. "What has ever happened to the gold of the Bank of Greece, some of which you thought might be left in our custody in Paris or elsewhere?" inquired McGarrah, who, as the president of the BIS might have been expected to know what it held and where.[10] It might, McGarrah suggested, be a good time to find the Greek gold and place it with the BIS.

The BIS, wrote McGarrah, could give the Bank of Greece "all sorts of facilities, rather greater than those of a local Central Bank."[11] For example, if the Bank of Greece held gold at the Bank of France and wanted to buy another currency, it first had to buy francs from the Bank of France. The Bank of Greece then converted the francs to the second currency, with all the usual losses of exchange rates and commissions. However, if the Bank of Greece held gold at the Bank of France in the name of the BIS, the BIS could "give the Bank of Greece any currency it desires at any time and can fix an agreed rate without going through the actual exchange operation."[12] And, the BIS did not charge any commission.

Thirteen thousand people applied for jobs at the BIS, and by the end of 1930 ninety-five people worked there. However, few were bankers—many were lawyers or economists who had previously been employed at international organizations such as the League of Nations or the Dawes Plan Agent General's office. Salaries were comparatively high: the president received $36,000 plus $14,000 entertainment allowance. Heads of department were paid between $15,000 and $20,000 a year, all tax free. (The average American salary in 1930 was about $2,000 a year.) The management reflected the balance of nationalities: the general manager, Pierre Quesnay, was French and a former member of the Young

Committee. His German deputy, Ernst Hülse, had worked for the Reichsbank.

But not everyone was happy. Hjalmar Schacht, who loved to refer to the BIS as "my bank," continued to rage over the scale of reparations under the Young Plan. In December 1929 he wrote to J. P. Morgan that he would not take up his directorship at the BIS. The following March, Schacht resigned from the Reichsbank. Hans Luther, a former minister of finance and former German Chancellor, replaced him. Schacht returned to his old métier: public relations. That autumn he went on a lecture tour across Europe and the United States. He passed the time during the journey across the Atlantic by reading Adolf Hitler's *Mein Kampf*. The style was crude and hectoring, he believed, but the author displayed a "keen brain."[13] Wherever Schacht spoke, he gave the same address: fulminating against the Young Plan, the Versailles Treaty, and reparations. He even appeared with John Foster Dulles at a dinner hosted by the Foreign Policy Association at the Astor Hotel in New York. Dulles played down the German elections in September 1930 in which the Nazis won 107 seats, making them the second largest party. The "difficulties" claimed Dulles, "are of a character which are largely psychological and consequently subject to ready reversal."[14]

Dulles's prediction was widely shared by his fellow financiers, especially those in Germany. Hans Luther, the new Reichsbank president, was especially keen to reassure his American colleagues that the surge in Nazi support would not disrupt the smooth flow of international finance. On September 22, eight days after the German election, Gates McGarrah, the BIS president, wrote to his friend and former colleague at the New York Federal Reserve, George Harrison, who was now its president:

> *We have the strongest assurances from Dr. Luther that we need not be disturbed about the result of the election. . . . The German people are not revolutionary and in our opinion anything beyond occasional street brawls will be summarily dealt with.*[15]

Not everyone shared McGarrah's faith. Investors rushed to sell Reichmarks. Paradoxically, the political and financial uncertainty was good for the BIS, giving the new bank an early opportunity to intervene in the money markets. The bank launched a rescue operation for the German currency. The next day, on September 23, McGarrah sent a telegram to Harrison: "Confidentially we intervened today on several markets to the tune of £300,000 with very helpful psychological effect, including cessation of offer of marks."[16] But in thinking that the reparations issue would settle down in Germany under the BIS's influence, Luther and McGarrah were wrong. The Young Plan, like German democracy, was a terminal case.

ON MAY 19, 1931, McGarrah presented the BIS's first annual report to the first general meeting. He noted that the bank had assisted with international financial operations and capital movement, where the "opportunities for constructive service are almost boundless,"[17] then he turned to the numbers. Profit making, noted McGarrah demurely, had "never been a primary object" of the BIS—which surely made him a banker unique in history. But he was pleased to report that thrifty investing during the bank's first ten and half months of existence had brought net profits of 11,186,521.97 Swiss francs. He noted that shareholders had increased from the original seven to twenty-three, including the national banks of Greece, Romania, Hungary, Latvia, Lithuania and Estonia, Sweden, and Czechoslovakia. The small, new European countries such as Czechoslovakia—a fragile construct carved out of the remains of the Austro-Hungarian empire—doubtless hoped that a stake in the BIS would bring stability, credibility, an improved standing in the sinternational community, and even a measure of defense against predatory neighbors. It

would prove to be a faint hope.

But for now the bankers were celebrating. Norman and Schacht had invented a perpetual money machine.

"The post of Head of Section in the BIS is for Germany's foreign policy definitely as important as the posting of many ambassadors accredited with foreign governments."

— Karl Blessing, Reichsbank official, 1930[1]

Schacht's colleagues in Berlin had a very particular view of the role of the BIS—one quite different to that which the Allies had envisaged when signing the Hague Convention. The bank set up to administer reparations was to be used to wreck them. Karl Blessing, a protégé of Schacht, wrote a lengthy memorandum in April 1930, setting out policy on the BIS. "Opinion on how the Reichsbank should conduct itself in the BIS" called for Germany to gain as much influence at the BIS as possible. German employees of the bank, Blessing wrote, should make sure that "no important business decisions are made without a German representative having knowledge of them or having had an opportunity to express their opinion."[2] Blessing recognized the bank's importance for Germany's national interest. He called for Germany to fill its posts in the bank with the most able and perceptive individuals.

All BIS member states wanted to protect their national interests in the new international forum. But Blessing understood what many bankers did not: that while the BIS might portray itself as neutral, objective, and technocratic, the bank was an inherently political institution, dealing with one of the most contested and bitter issues in politics—German war guilt and reparations. Blessing wrote, "The fact that the reparation question has been delegated to a banking institution naturally turns this bank into a political institution, even if this is officially denied."[3]

France and Britain might believe that the establishment of the bank settled the reparations issue, but Blessing understood that the existence of the BIS actually offered a forum to open up the issue once again. Blessing's savvy ruthlessness was in sharp contrast to Montagu Norman's notion of a cozy club. The Reichsbank, Blessing argued, should certainly cooperate with the BIS in its new role as the bank for central banks. As a trading nation that relied on exports, Germany could only benefit from an improved international economy. Reparations, however, were an entirely different matter.

Blessing called for German officials to undermine the new bank by making impossible demands that would sour the atmosphere and weaken its credibility. He demanded a sophisticated form of psychological warfare against the BIS. German officials there must "time and again refer to the completely utopian objectives of the bank." German bankers should repeatedly ask the BIS to guarantee export credits for high-risk ventures, even when it was clear that the credits would never be granted. The aim was to "gradually create an atmosphere in the Bank in which the anti-reparation bacillus finds fertile ground."[4] If the bank began to lose legitimacy, then so surely would the Young Plan, which the bank was mandated to administer. In 1931 Blessing left the Reichsbank to take up a senior post at the BIS.

But even with Blessing on board, the BIS could not solve the German financial crisis. The elections in 1931, which saw the Nazis and Communists win one-third of the seats in the Reichstag, had made the country almost ungovernable. That political instability triggered capital flight, which caused a further rise in unemployment and a lack of confidence in both government and the banking system and led to further capital flight, higher unemployment, and more support for the Nazis and the Communists. The Weimar Republic had entered its death spiral.

In June 1931 Chancellor Heinrich Bruning declared that he doubted if Germany could meet the next payment due under the Young Plan. The situation was so grave President Herbert Hoover called for a moratorium on all war debts and reparations. It was agreed, for one year. The Bank of England, the Bank of France, the New York Federal Reserve, and the BIS agreed on an emergency loan to Germany of $100 million.

As Toniolo notes, the "newborn BIS was at the heart of the first experiment ever of a multilateral attempt at managing an international financial crisis."[5] It was not successful, but then it was never likely to be. Fixing the German debt crisis was a task far beyond the BIS, even if the BIS had been created expressly for the purpose of facilitating reparations.

In December 1931 the German minister of finance wrote to the BIS, saying that as Germany was suffering a "crisis without parallel" the bank must re-examine the whole question of reparations. The BIS set up a committee, headed by an Italian board member, Alberto Beneduce, to examine the matter. Carl Melchior, a prominent German Jewish banker and vice chairman of the BIS, represented Germany. Melchior had served as a captain in the German army in the First World War, in which he was badly wounded. A skilled diplomat and financier, Melchior had been a member of the German delegation at the Paris Peace Conference in 1919. He had represented Germany on the Young Committee and chaired the finance committee of the League of Nations. His tact and skills had helped Germany re-enter the community of nations. The Beneduce Committee's conclusions, published just before Christmas 1931, were a triumph for Berlin. All intergovernmental reparations and war debts must be "adjusted" to ensure peace and economic stability. "Adjustment" was a euphemism for abolition. Six months later, in 1932, European governments met in Lausanne to consider the Beneduce Committee's recommendations. They agreed to cancel German reparations, except for one final payment.

THE BIS PRESENTED itself as a new and modern institution, but central banks and war had been entwined through history. The Bank of England had been founded in 1694 in part to raise funds for King William III's war against France. The bank accepted deposits and issued personal notes against the funds, which could be redeemed for gold. Clerks added the customer's personal details to the document, the precursor of today's banknotes. A little more than a century later, in 1800, Napoleon Bonaparte founded the Bank of France. The emperor aimed to bring about stability and economic growth after the wars and revolutionary turmoil of the late eighteenth century. The Reichsbank was founded in 1876 in part to finance future German expansionism, after the Franco-Prussian war of 1870 had triggered a liquidity crisis. The German bankers had planned ahead. A law suspending gold convertibility of Reichsmarks in time of war was drafted in 1904.[6] By the summer of 1914, the approaching war had triggered a run on the Reichsbank reserves. In July the Reichsbank lost 103 million marks in a week. The bank suspended gold convertibility, which was an illegal act. Parliament passed an act retrospectively authorizing that decision four days later.[7]

Yet there was also an argument in favor of empowering the financial technocrats to get on with running the global economy, unbound by political considerations. It was the politicians and governments, some of them democratically elected—not the bankers—who had led the world to war and caused the deaths of millions. The bankers would finance their political masters' conflicts, as they were required to do, but they had no desire to order men to walk into a hail of bullets to gain an inch of mud-soaked field in Belgium. Rather, the central bankers shared similarly benign aims: stability, economic growth, and increased prosperity for all. The central bankers formed a global brotherhood, united by common bonds that transcended parochial national interests. In an era when nationalism had ripped apart the old European order, perhaps the bankers' transnationalism could bring peace. The BIS, had after all, been

specifically designed in the aftermath of war for that purpose. By managing Germany's reparation payments and acting as a trustee for the Dawes and Young loans that had allowed Germany to meet its international obligations, the bank should, theoretically, defuse the explosive German question.

The bankers' personal friendships could be deep and enduring. The bond between Norman and Schacht, for example, lasted for almost thirty years, until Norman died in 1950. It outlasted the hyperinflation of the early 1920s, the stock market crash of 1929, the collapse of the Weimar Republic, the rise and fall of the Third Reich, Schacht's trial at Nuremberg for war crimes, the disintegration of the British Empire, the onset of the Cold War, and the division of Germany. Such deep connections between powerful men were rare and potentially valuable.

Even the BIS's more nebulous mandate of central bank cooperation had its defenders. Economists and bankers had long argued that as the world economy became more sophisticated, and central banks became more powerful, there was a need for some kind of coordinating body to ensure financial stability. Julius Wolff, a professor at the University of Breslau, had proposed in 1892 that a new financial institution in a neutral country be set up to issue an international currency. The new unit would be backed by central banks' gold reserves and be used for emergency lending to countries in crisis. Luigi Luzatti, an Italian politician, wrote in 1907 in the Viennese newspaper *Neue Freie Presse* that central banks were waging an unnecessary "monetary war" by competing for gold supplies by raising interest rates and other devices. It would be far better, he posited, for banks to adopt a policy of "cordial cooperation" by supplying gold to those banks that needed it. He called for a new commission to coordinate "international monetary peace," since even when central banks did lend to each other, national interests colored those loans. Thus there was a need for a technical, apolitical institution to handle these transactions, a financial equivalent of the postal and telegraph unions. The BIS seemed to fit the bill.

The bank was also a creature of its time, of new multilateral institutions run by apolitical technocrats. The League of Nations, which was the forerunner of the United Nations, would defuse the world's political crises, while the BIS would ensure financial stability. Pierre Mendes-France, a French Socialist politician, wrote in July 1930, that the BIS, after administering the Young Plan, "will progressively increase its patch and little by little the experience will show the areas that it may approach safely."[8] Mendes-France, who served as prime minister in the 1950s, praised the BIS and the League as the potential harbingers of peace. "In the mists of the future, the mystical purpose of a union in financial order . . . under wise and prudent management," he wrote, "may become a potent aid for the preservation of world peace."[9]

The US government took a very different view. The BIS was born out of reparations negotiations chaired by two Americans, Charles Dawes and Owen Young. Its first presidents, Gates McGarrah and Leon Fraser, were American. But Henry Stimson, the secretary of state, proclaimed that the United States did not wish to "directly or indirectly participate in the collection of German reparations through the agency of a bank or otherwise."[10] The United States had never asked for reparations, thus it had no reason to participate in the BIS. It had not even joined the League of Nations, even though President Woodrow Wilson had practically invented the institution. The State Department's opposition to the BIS was so strong that George Harrison, the governor of the New York Federal Reserve, even avoided Basel when he traveled to Europe. Washington, DC, refused the BIS directorship offered to the Federal Reserve. The consortium of American banks—J. P. Morgan, the First National Bank of New York, and the First National Bank of Chicago—that had bought shares at the bank's founding took up the directorship instead.

Eleanor Lansing Dulles, however, was firmly in the internationalist camp. She published her book on the BIS in 1932, despite some difficulties when she was rumored to be an American spy and then lost her office and access to internal documents. McGarrah, the bank's president, wrote of his regret to John

Foster Dulles that the bank could not have been more open to her. "I am sorry not to have been able to be more useful to your sister, and we would have been glad to open everything up to her, including an office here, but . . . the work of this bank, like that of any other is in large measure confidential."[11]

Eleanor Dulles was by far the most attractive of the Dulles siblings. She was a feisty career woman with a sharp mind of her own in an age that did not welcome such women. Her personal life was marked by tragedy—a pronounced anti-Nazi, she fell in love with David Blondheim, a Jewish intellectual, and married him, to the dismay of her family. He later committed suicide. Eleanor Dulles went on to enjoy a stellar career in the US Foreign Service, specializing in Germany. In *The BIS at Work*, she described a smooth-running institution, a kind of financial League of Nations, where different nationalities worked in harmonious cooperation. The bank was a future model for the world and should have been granted stronger powers to prevent national interests asserting each themselves. "If the BIS is not given the power and the facilities to work at this problem the result will be the emergence of financial rivalries," she warned.

> *One central bank after another will gain a predominating influence and as this central bank is threatened from time to time by rival financial influence, the stability of the economic system will be strained to the breaking point again as it has been in 1931. It is to avoid such catastrophes that the BIS should be strengthened to meet the urgent needs which lie before it.*[12]

Unfortunately for Eleanor Dulles and her fellow idealists, Blessing and Schacht's plan for the BIS was about to come to fruition. The new regime in Germany would exploit the BIS's supranational reach to advance its own national interests. By April 1933 the Nazi terror had begun in earnest. Legalistic as ever, the German legislators had voted their democracy out of existence. The Enabling Act, passed by the Reichstag the previous month, removed citizens' rights to free speech, assembly, travel, and protest. It permitted arbitrary arrest, torture, and detention. Germany was now a racially based dictatorship. On April 1 Nazi stormtroopers ran riot across the country, barricading the entrances to Jewish shops, daubing them with Stars of David and slogans that called on shoppers not to buy from Jews. The first prisoners began arriving at Dachau, the SS's prototype concentration camp.

Soon after the April pogrom—the clearest signal yet of the Nazis' intentions for Germany—Hitler asked Schacht if he would return to his old job as president of the Reichsbank. Schacht accepted and so regained his seat on the board of directors of the BIS. Schacht was a conservative German nationalist, rather than a believer in Aryan racial supremacy. Jews, he believed, were rather too pushy, but could still be useful for the economy. Schacht tolerated, rather than advocated Hitler's anti-Semitism. Schacht used his privileged position to occasionally speak out against the campaign against the Jews, but he was no anti-Nazi. He wanted a strong, economically independent Germany. If Hitler offered the best chance for that, then so be it. Back in 1930 Schacht had told Bella Fromm, a Jewish society columnist, "Why not give the National Socialists a break? They seem pretty smart to me."[13] Now he had the opportunity to do so.

The Nazis also seemed "pretty smart" to the BIS's American management. "Order and discipline in Germany are at the present time exemplary," wrote Gates McGarrah to Leon Fraser in 1933. "The vast majority of the population has the feeling that the fortunes of Germany are in the hands of strong leaders who are inspired by goodwill, so that an optimistic view as regards the future development is justified."[14] The German order, discipline, and goodwill that McGarrah so admired came at a high price, although he did not have to pay it. Carl Melchior did.

As McGarrah eulogized the new Germany, his colleague Melchior, the vice president of the BIS, was forced by the Nazis to resign. The fate of the eminent Jewish banker was regrettable, they murmured in Basel, especially after three years of loyal service, but there was nothing to be done—and certainly not by the BIS, which must remain neutral in its members' internal affairs. Leonardus Trip, the president of the Bank of the Netherlands, swiftly replaced Melchior. The Dutch banker's elevation left a vacancy on the bank's board, which was filled—as it was noted in the BIS 1933 Annual Report—by "Baron Curt von Schröder of the banking house of J. H. Stein, Cologne."

This terse description rather undersold the German nobleman. Kurt Freiherr von Schröder (his name is usually spelled with a "K") was one of the most powerful and influential bankers in Nazi Germany, a scion of the dynasty whose empire included J. Henry Schröder in London and Schrobanco in New York, whose board Allen Dulles joined in 1937. Sociable, cosmopolitan, and well-traveled, von Schröder was known as a reliable, international financier, part of the new global elite who were equally at home in the gentlemen's clubs of London or the dining rooms of Wall Street. The German banker was especially close to Frank Tiarks, the director of the Bank of England who was a partner in J. Henry Schroder bank in London. Tiarks had set up Schrobanco in New York, recruiting Gates McGarrah to its board. Between 1923 and 1939 Kurt von Schröder regularly traveled to London and frequently met Tiarks. The two men had "many business talks together," von Schröder later testified. While in London, von Schröder arranged loans for the Flick industrial concerns, whose head, Friedrich Flick, was pouring money into the Nazi party. The loans, like most of Kurt von Schröder's arrangements, went through his relative Baron Bruno von Schröder, the head of the London branch of J. Henry Schröder banks. Kurt von Schröder also did business with several other major British banks, including Guinness Mahon, Kleinwort, and Lloyds, all on behalf of J. H. Stein, the influential private bank in Cologne where he was a partner.[15]

Hjalmar Schacht personally appointed von Schröder to the BIS board. The summons came out of the blue. "Mr Schacht called me up one day in Berlin and said that they must have a new man for the BIS and told me he thought I was the right one. . . . I was very surprised," von Schröder told Allied interrogators in 1945.[16] Such modesty was unconvincing. Von Schröder enjoyed close personal links with the highest reaches of the Nazi party. He had helped to bring Hitler to power. In January 1933 von Schröder had hosted a meeting at his villa in Cologne between Hitler and Franz von Papen, the former chancellor, who later served as Hitler's vice chancellor. Rudolf Hess, Hitler's deputy in the Nazi party; Heinrich Himmler, the chief of the SS; and Wilhelm Keppler, Hitler's fundraiser and liaison with German businessmen were also there. Keppler later ran the Himmlerkreis, the circle of businessmen who channelled money to Himmler's slush fund at the J. H. Stein bank.

At the meeting, Hitler outlined his plans for economic autarky.[17] Germany could no longer be dependent on foreign countries for any of its needs. The country must be self-sufficient—especially in synthetic oil and rubber. Without these Germany could not wage war, Hitler announced. Production of synthetic oil and rubber was the responsibility of IG Farben, the giant Nazi chemicals conglomerate, which is why Hermann Schmitz, the CEO of IG Farben, would later join Schacht and von Schröder on the board of the BIS. During the war Schmitz channeled money to Himmler via Schröder into special account "S" at J. H. Stein bank, British intellience documents reveal. In 1941 alone, Schmitz transferred 190,000 Reichsmark into the SS leader's personal account. Himmler appreciated Schmitz's generosity, Schröder wrote to his fellow BIS board member, asking Schmitz to transfer a similar sum:

> *I, therefore, take the liberty of asking you again, this year, to remit the same amount for the Reichsführer-SS to the Special Account "S" with the banking firm of JH Stein, Cologne. I would be grateful to you if you complied with this request. As you know, the Reichsführer has*

always particularly appreciated this contribution and you may be sure of his gratitude.[18]

Carl Melchior, who had served his country and the BIS so diligently, had been long plagued by ill health, and he died in December 1933.

ON WALL STREET, Hitler's rise was watched with fascination and concern. Fascination because the advent of an extreme nationalist, one-party state in Germany seemed to have finally banished the specter of Bolshevism. But were Wall Street's investments and holdings really safe? Substantial sums were at stake, involving the most powerful companies in America, several of which were deeply entwined with IG Farben. The German firm operated in the United States as General Aniline and Film (GAF). GAF's founding board members included Walter Teagle, Standard Oil's president; Edsel Ford, the president of Ford Motors; Charles E. Mitchell, chairman of the National City Bank; and Paul Warburg, of the banking dynasty. Standard Oil was GAF's most important partner, and the two firms signed a research and development agreement on oil production. (Standard Oil was also on excellent terms with the BIS—Robert Porters, the bank's chief administrative officer, left to become an adviser to the oil company.)

Standard Oil owned the patents on synthetic rubber, known as Buna, but had ceded control of them to IG Farben. In 1929 Walter Teagle had agreed to a "division of fields" cartel arrangement with its German partner. "The IG are going to stay out of the oil business and we are going to stay out of the chemical business," explained one Standard official.[19] The Standard Oil–IG Farben agreement set the pattern for a series of powerful cartels. John Foster Dulles carried out much of the pioneering legal work for these. Sullivan and Cromwell represented General Aniline and Film, IG Farben's American subsidiary.

Dulles was a director of the International Nickel Company (INKO), the largest producer of the metal in the world. In 1934 INKO signed a cartel agreement with IG Farben, swapping supplies of nickel sources for the license rights to a newly patented nickel-refining process.[20] Dulles also arranged chemical cartels. He represented the Solvay American Investment Corporation, the American subsidiary of a Belgium firm that was a partner of IG Farben. Solvay American held 25 percent of the stock of the Allied Chemical & Dye Corporation, an American company. In 1936 Allied entered a cartel agreement with IG Farben on dyestuff production. And so it went, all through the 1930s, as American financiers and lawyers —none more than John Foster Dulles—ensured that American money, commodities, and expertise flowed steadily into the Third Reich.

But there was still some unease in the boardrooms and clubs, not because of the persecution of the Jews or the concentration camps, but because the Nazi party seemed to still have some dangerous tendencies: its full name, for example, translated as the German Nationalist Socialist Workers' Party. The Brownshirts, the Nazi "leftist" faction, remained powerful. The bankers and industrialists needed fresh, firsthand reassurance. They needed a meeting with Hitler.

Wall Street's envoy was Sosthenes Behn. On August 4, 1933, the *New York Times* reported that Hitler had held his first meeting with "representatives of American finance." The newspaper noted, "Chancellor Hitler, who is resting at his mountain retreat on the Salzburg, today received Sosthenes Behn, a director of the National City Bank of New York, and Henry Mann, its resident vice president for Germany. . . . There was no hint of the motive." But there did not need to be. Behn had founded the International Telephone and Telegraph Company (ITT) in 1920. ITT had grown to be one of the most powerful companies in the world. It had substantial holdings in Germany, some of which were engaged in armaments production. ITT needed a well-connected banker there to look after its interests and subsidiaries. It found one—in Kurt von Schröder.

SCHACHT SOON TURNED on the bank he had helped create. The 1932 Lausanne conference had canceled Germany's obligations to pay reparations to the Allied victors. But the loans Germany had taken out under the Dawes and Young plans to meet those obligations were still outstanding. It was of little concern to the Wall Street financiers whether Germany used their funds to pay for reparations or to fund a new armaments drive. They wanted to know that they would get their money back. Schacht told the BIS governors at the June 1933 board meeting that he supported paying the Dawes loan but not the Young loan. Germany simply did not have sufficient resources to pay them both. Schacht was under intense political pressure from the Nazi leaders, who wanted both loans written off, seeing them as the final vestiges of Germany's humiliation at Versailles.

The creditors, naturally, disagreed. Another conference was called, this one chaired by Leon Fraser, the BIS president, and hosted by the Reichsbank in Berlin in May 1934. The Berlin gathering was a total failure. Soon afterward Germany announced a complete moratorium on all medium- and long-term debts, including the Dawes and Young loans. The announcement caused fury as bondholders saw their assets vaporize. J. P. Morgan even suggested that the BIS stake a claim to German funds held in Switzerland. That was neither realistic nor practical. The BIS could do nothing except issue a protest against what Fraser called the "thoroughly arbitrary way in which the German government has disregarded its engagements."[21]

It had no effect, for the old fox, as Schacht was known, had outmaneuvered everybody with a high-stakes game of international poker. The Reichsbank governor understood that a blanket default would severely damage Germany's international standing and credit-worthiness. Yet it was imperative to disentangle Germany from the obligations of the Dawes and Young plans and all the political and emotional baggage that they brought in their wake. The policy of economic autarky outlined at the meeting at Kurt von Schröder's house and the memo written by Karl Blessing back in 1930 demanded no less. So as soon as Germany had broken free from the BIS, Schacht swiftly concluded bilateral agreements with Dawes and Young loan bondholders in seven countries, including Britain, France, and Italy, albeit at reduced rates of interest. It was the old principle of divide and rule, brilliantly applied to the new field of international finance. Just as the rule of law had been torn up in Germany, so had the country's international financial obligations.

Schacht's arbitrary rewriting of Germany's debt obligation proved that Germany's commitments were not worth the paper they were written on. At the same time, the dealings of some of those working in the BIS also seemed less than scrupulous: the combination of secrecy, insider information, and vast amounts of money sloshing around was having unwelcome effects. Some of the BIS staff were, it seems, insider trading. Basel was full of rumors that BIS officials were using their privileged knowledge of the bank's activities to speculate against the Swiss franc. A hard-hitting article in the *Berner Tagblatt*, a Swiss newspaper, in May 1935, had caused uproar, especially as it appeared to be based on documentation or a high-level source inside the BIS. Swiss bankers widely believed that the BIS had no confidence in the Swiss franc. A Swiss MP had even raised the conduct of the BIS in the Swiss Parliament. The situation was getting uncomfortable for the BIS management.

The following month the staff was questioned one by one. Gates McGarrah, who had stepped down as president, but remained on the board, wrote to Johan Willem Beyen, his Dutch colleague and fellow board member, that the investigation had turned up some alarming information. One of the bank's "higher officials" had bank accounts in both London and Switzerland, both of which had been overdrawn on the security of stocks and shares. The staff member had been shorting sterling and Swiss francs—selling the currencies when strong and buying them back when they weakened. "This, of course, is a clear case of currency speculation," admitted McGarrah, but there was no need to take any action, he wrote. If the

banks do not object and the overdrafts were long-standing, "it might be difficult to criticize too harshly or to interfere with any vigor in the private affairs of a man of some standing who is endeavoring to look after his own fortune in the way he considers best."[22] In other words, even though the senior BIS official was indeed speculating, nothing should be done, especially as he was a man of "some standing."

Another case, which even the emollient McGarrah noted "calls for comment," involved a member of staff who borrowed money in London to buy gold. Alarmingly, the BIS staffer did this, he explained when questioned, "at the same time as his chief." Such practices were "highly undesirable," argued McGarrah, especially as the staffer's chief was a member of the BIS management (it is not clear who from the documents).[23] Thus, the BIS was in no position to issue an official denial about speculation, McGarrah continued. The bank's best option was to inform the Swiss National Bank that it had received the assurance of its management and staff that no speculation had taken place (even though it had) and that the bank would take measures against the possibility of it happening in the future. Bankers in the 1930s, like many of their present-day contemporaries, wanted any potential scandal about their personal probity shut down as soon as possible. "It might be best to endeavor to let the matter die a natural death outside the house and to proceed only with a further internal investigation," McGarrah noted.[24]

> *"The above-mentioned young Nazi and his friends believe that the BIS offers them their best contact with the outside world. They want to have capable representatives in the BIS in order to break the way for [an] approach to more normal business and monetary relations with the important countries of the world."*
>
> — Merle Cochran, an American diplomat who monitored the BIS, in a telegram to the State Department, May 9, 1939[1]

The *Berner Tagblatt* newspaper's revelations about the murky goings-on inside the BIS highlighted the growing questions about the bank's role and function. Insider trading during the 1930s was often the rule rather than the exception, but there were wider issues at stake. The BIS had been established for three main purposes. The first, and ostensibly the most important, was to manage German reparations payments under the 1930 Young Plan. The second was to facilitate cooperation between central banks. And the third was to act as a bank for central banks. The BIS was barely five years old in 1935, but it had already had lost its primary reason for existence and the second reason was under threat. How long would it be before the third reason—to act as a central bank for banks—was called into question?

The Young Plan had collapsed almost as soon as it was agreed to. The Hoover Moratorium, announced a year later, had paused reparation payments. The 1932 Lausanne Conference had confirmed that Germany's war debts would be written off. Thus, there were no more reparations payments. The BIS was also the trustee for the loans that Germany had taken out under the Dawes and Young plans to make those reparations payments. But Gemany had stopped using the BIS to repay the Dawes and Young plan loans. Instead Schacht had blackmailed Germany's creditors into signing new bilateral agreements. The Reichsbank, a cofounder of the BIS, had broken its legal, financial, and moral obligations with complete impunity and delivered a serious blow to the BIS's credibility as a neutral interlocutor.

So for what other reasons did the BIS continue to function? It acted as a facilitator of central bank cooperation for countries whose currencies were on the gold or gold exchange standard. (The gold standard valued a national currency at a set amount of gold. The gold exchange standard included the country's holdings in US dollars and British pounds as part of its national reserves.) The statutes of the BIS assumed that international finance was based on the gold and gold exchange standard and so would continue to grow smoothly and steadily, facilitated by the bank. As Toniolo notes, "The gold standard was embedded in the very DNA of the BIS."[2] The bank kept its accounts in Swiss gold francs, with each franc worth 0.29 grams of fine gold. But the central banks were losing their enthusiasm for gold. Even Britain had come off the gold standard. By the end of 1932 only seven of the forty-six countries that had been on the gold standard remained, including France, Italy, and the United States, which left the following year.

With no more reparations and the collapse of the gold standard, why did the BIS stay in business? In part—as others who wished to dissolve the bank would find in later years—because it was founded under an international treaty, and its statutes were essentially immutable. Schacht and Norman had designed their bank superbly. It was not possible to close the BIS. In fact, the end of reparations and the collapse of the gold standard proved a boon for the BIS. It allowed the bank to focus on its founders' intentions: to

build a new transnational financial system of large capital movements, free from political or governmental control. Gates McGarrah, the bank's first president, had explained as much soon after the bank was founded. Writing in *Nation's Business* magazine, McGarrah admitted that German reparations payments were a "routine operation," which any trust company could administer.

> *The conception seems to have formed in the popular mind that the Bank for International Settlements, which began at Basel, Switzerland, May 20, 1930, was organized merely to handle German reparations payments and the so-called inter-allied debt and that its principal operations are concerned with the German debt payments. That is a mistaken, although an understandable, view.*
>
> *Although the prime reason for the bank's creation was to administer the monthly sums paid into it by Germany, this duty has already become the smaller side of the Bank's activities. The handling of the German reparations payments is a routine operation, which any trust company could carry on. Within six months after opening for business the Bank has developed much larger and more important activities and has become a medium of service, which is one of the saving features in a tense world situation. . . .*
>
> *The Bank is completely removed from any governmental or political control. No person may be a director who is also a government official. The Bank is absolutely non-political and is organised and operated on a basis purely commercial and financial, like any properly managed banking institution. Governments have no connection with it nor with its administration.*[3]

McGarrah, like every international financier, regarded the Bolshevik Revolution with horror. Yet he and Vladimir Lenin had much more in common than either could know. The BIS president and the Russian revolutionary both understood that the twentieth century would be the bankers' century. The new mechanisms of transnational capitalism allowed the bankers to send vast sums of money quickly and easily around the world and harvest vast profits from doing so, free from oversight.

The bankers could save a country from collapse and revive its economy—as they did in Germany in the early and mid-1920s, dispatching hundreds of millions of dollars and underwriting the Dawes loan—or they could help send it into a tailspin, by stopping the flow of cash and then pulling out, as they did at the end of the 1920s.

Massive capital movements were now increasingly common. The BIS, as the bank for central bankers, institutionalized that new power. In the first six months of 1931 the BIS advanced £3 million to the Bank of Spain to stabilize the peseta; gave a credit of 100 million Austrian schillings to the national bank when the Credit Anstalt bank went bust; and advanced $5 million to the Hungarian National Bank and arranged a further $10 million credit for Budapest. A small clique of financiers, unaccountable to any government, most of whom knew each other well, had somehow amassed unprecedented economic and political power. Lenin had understood the rising power of finance capital while he was living in exile in Zürich and working in his epic study of imperialism. "The old capitalism has had its day. The new capitalism represents a transition toward something," he wrote. "Thus the beginning of the twentieth century marks the turning point at which the old capitalism gave way to the new, at which the domination of capital in general made way for the domination of finance capital."[4]

ON JANUARY 5, 1939, almost two months after *Kristallnacht*—the state-sponsored pogrom against

Germany's Jews—Montagu Norman stepped off the train at the Zoologischer Garten station in Berlin and was met by Hjalmar Schacht. Norman was the guest of honor at the christening of Schacht's grandson, and he was swiftly driven to Schacht's apartment in the Reichsbank building where the ceremony took place. The baby boy was named Norman Hjalmar. Numerous articles in the German press welcoming Norman to Berlin heightened the friendly atmosphere. The two bankers then traveled to Basel together for the monthly board meeting at the BIS.

As Europe slid inexorably to war, British journalists and politicians were asking increasingly pointed questions about the close ties between Norman and Schacht. The Reichsbank president had been in London just before Christmas and had visited Norman at home. What had been discussed? The *News Chronicle* newspaper, for example, suspected that Norman might be an envoy, not just for the Bank of England, but for the pro-appeasement government, led by Prime Minister Neville Chamberlain. Why had he gone? What was Norman saying to the Nazi leaders in Berlin?[5] The newspaper demanded to know. Ernest Bevin, a powerful trade union leader, also wanted answers. "One cannot enter into financial arrangements between these great central banks involving the economic life of the respective countries, without it having a direct reaction on the liberties and rights of the people,"[6] he thundered—sentiments that are as true today as in 1939.

Bevin and the journalists were right to be suspicious of Norman's relationship with Schacht. The Reichsbank president, more than anyone else, had rebuilt Germany, a country that would soon be at war with Britain. Schacht had wrought a miracle—a centrally planned economy that was not ravaged by inflation, a worthless national currency, or unemployment. In the six years since Hitler had taken power, unemployment had been reduced from six million to around three hundred thousand. Armies of the jobless were diverted to massive programs of public work—building the new network of motorways, gigantic public buildings, and planting forests. Arms production was soaring. Trade unions no longer existed and were replaced by the state-run German Labor Front (DAF). The work-shy, along with Jews, leftists, and others viewed as undesirables were dispatched to concentration camps.

Germany adored its miracle maker. In January 1937, on the occasion of his sixtieth birthday, Schacht had stood for four hours receiving hundreds of guests. Hitler himself sent a personal message praising him. Schacht told Hitler's adjutant, who had brought the message, "Tell the Führer that he has no more loyal co-worker than I." Schacht's admirers believed, correctly, that without him, Germany would still be weak, poor, and, worst of all, humiliated. "Every branch of German finance, commerce, industry, and society and the armed forces was represented. There were bankers, manufacturers, merchants of all grades, big and little," the *New York Times* reported. Hitler gave Schacht a painting by Carl Spitzweg, a German romanticist painter. Montagu Norman sent a mahogany clock.[7]

Schacht's real job was to prepare Germany for war. In his correspondence with Hitler, Schacht repeatedly emphasized the importance of the armaments program. In May 1935 he wrote,

> *The following comments are based on the assumption that the accomplishment of the armament program in regard to speed and extent, is the task of German policy, and that therefore everything else must be subordinated to this aim, although the reaching of this main goal must not be imperiled by neglecting other questions.*[8]

That same month Hitler appointed Schacht General Plenipotentiary for the War Economy. For all his old-world manners and elegant appearance, Schacht was a state-sanctioned crook, licensed by Hitler to tear up contracts, steal, extort, and fiddle the Reichsbank's books, which was why he got the job. Schacht funded rearmament by inventing a piece of financial chicanery known as the "MEFO" bill, which allowed

the state to illegally borrow billions of Reichmarks from the Reichsbank—a policy Schacht later described as "daring." He hijacked the blocked funds of foreign depositors in the Reichsbank. He requisitioned German residents' foreign currency holdings and ruled that all foreign currencies received as payments for exports must be sold to the Reichsbank. He fiddled the capital markets so that foreign firms could not compete on equal terms with German competitors. He could outsmart anyone, even the wily Jews, proclaimed Hitler:

> *Before each meeting of the International Bank at Basel, half the world was anxious to know whether Schacht would attend or not, and it was only after receipt of the assurance that he would be there that the Jew bankers of the entire world packed their bags and prepared to attend. I must say that the tricks Schacht succeeded in playing on them really provide that even in the field of sharp finance a really intelligent Aryan is more than a match for his Jewish counterparts. In spite of his ability I could never trust Schacht for I had often seen how his face lit up when he had succeeded in swindling someone out of a hundred mark note.*[9]

Schacht was a creature of his time. The dreams of the internationalists who believed that the BIS, like the League of Nations, would engender global peace and harmony were dead. Invasion, annexation, and mass murder were the new tools of international empire building. The Third Reich was rising and would last a thousand years, proclaimed Hitler. Austria had been forcibly incorporated into the Third Reich in the Anschluss of March 1938—with little objection from its citizens. Italy had invaded Abyssinia (now Ethiopia) and was dropping poison gas on defenseless civilians. Japan was laying waste to Manchuria, having murdered hundreds of thousands during the Rape of Nanking in 1937. Neville Chamberlain, the British prime minister, had signed the Munich agreement that ceded the Sudetenland, a province of Czechoslovakia, to Germany. The Spanish civil war, with its flattened, charred cities, its savage brutality and atrocities, was a precursor of Europe's fate.

Yet even as he rebuilt Germany's economy, Schacht must have asked himself if the price was really worth paying. He did not believe in the Nazis' ideas of racial supremacy and refused to join the party. Rather, he was an authoritarian national conservative. He had made a deal with the devil to see his homeland rise again from, as he saw it, the humiliation of the Treaty of Versailles and the penurious obligations of the Dawes and Young plans. Like many Germans of his class, Schacht tried to rationalize the Nazis' brutality and anti-Semitism until the contradictions could be borne no longer. In the summer of 1938, he turned to his partner at an elegant dinner in Berlin and asked, "Madam, how could I have known that we have fallen into the hands of criminals?" He might have been addressing the question to himself, for after five years of Nazi rule the answer was there in front of him—if he had chosen to look.

By 1938 Schacht had begun to play a perilous game, using the BIS as a secret back channel to Britain to try and bring down Hitler and stop the march to war, or so he claims in his memoirs. Schacht first approached several senior military leaders to encourage them to launch a coup. None would agree. That left the monthly meetings at the BIS. "The more conditions in Germany approached a climax, the greater my desire to make use of my connections in Basel as a means of preserving peace," he wrote.[10] The Reichsbank president took Montagu Norman aside at a BIS meeting and asked him to approach Chamberlain to set up a channel between London and the anti-Nazi Germans. Four weeks later Norman and Schacht met again in Basel. Norman told Schacht that he had discussed his proposal with Chamberlain. Schacht asked what was his reply. Chamberlain had said, "Who is Schacht? I have to deal with Hitler."[11]

After Kristallnacht, even Schacht's self-deception and rationalization began to fade. The attack on Germany's Jews, Schacht proclaimed in his speech to the Reichsbank Christmas party, was "such a wanton and outrageous undertaking as to make every decent German blush for shame. I hope none among you had any share in these goings-on. If any one of you did take part, I advise him to get out of the Reichsbank as quickly as possible."[12] Schacht's indignation, whether real or feigned, was wasted. His Reichsbank was the Nazis' most important instrument for looting the assets of German Jewry. After Kristallnacht, the Nazis imposed a fine of one billion Reichmarks on German Jews, to be paid in four installments.

Schacht then proposed to Hitler a bizarre plan to help German and Austrian Jews to emigrate, the kind that only a banker could dream up. Jewish holdings in both countries would be placed in an international trust. The trust would sell twenty-five-year bonds—which would pay dollar dividends—to world Jewry. Part of the dividend would finance the emigration of German and Austrian Jews, and part would be used to boost German exports. Hitler agreed to the plan, but, not surprisingly, nothing came of it. Schacht did help save Bella Fromm, the high society Jewish journalist. Fromm had continued her acerbic observations of Berlin society, politics, and diplomacy, until the summer of 1938 when it became clear she had to flee. She was packed and ready to go when the paperwork got stuck for the transfer of her personal funds—this was a disaster, as without the monies she would not be allowed into the United States. She asked Schacht for help, and he rushed her case through the Foreign Exchange Office. Fromm immigrated to New York.

MEANWHILE, AS EUROPE slid to war, the atmosphere in Basel between the central bank governors remained "entirely cordial," reported Merle Cochran. Cochran traveled to Basel every month from his base at the United States embassy in Paris, to meet Montagu Norman and Hjalmar Schacht at the governors' meeting. He was not allowed to attend, but Norman and Schacht briefed him afterward on the discussions. Cochran then sent on the information to Henry Morgenthau, the Treasury secretary, and to the State Department. Cochran had excellent sources at the BIS, including Paul Hechler, the German assistant general manager, who signed his correspondence "Heil Hitler." Most of the central bankers had "known each other for many years, and these reunions are enjoyable as well as profitable to them," Cochran reported to Washington on May 9, 1939. "The wish was expressed by some of them that their representative statesmen might quit hurling invectives at each, get together on a fishing trip with President Roosevelt or at a World's Fair, overcome their pride and complexes, and enter into a mood that would make comparatively simple the solution of many of the present political problems."[13]

If only things were that simple. Basel at least was a safe haven from the world's vicissitudes. The governors' monthly meeting took place at 4 p.m. on Sunday, without notes or minutes being taken, after which high tea was served. The rest of the two days were busy with breakfasts, lunches, dinners, concerts, receptions, and walks along the Rhine and in the Black Forest. Bank officials' wives were also drafted to lighten the atmosphere at social events. Each governor—just as nowadays—was provided with his own office. The doors were closed while the governors were in discussions with their staffs but were otherwise left open so that bank staff and other governors could make social calls or drop by to exchange news and information.

The bankers began to see the broader picture—the global linkages between their decisions and their consequences. "As they sat down around the table for two days, you could almost see their point of view change as they began to realize the effect of their own actions," reported W. Randolph Burgess, deputy governor of the New York Federal Reserve.[14] Norman and Schacht were still the star attractions. Johan Willem Beyen, a Dutch banker and BIS president in the late 1930s, recalled,

Norman's prestige was overwhelming. As the apostle of central bank cooperation, he made the central banker into a kind of arch-priest of monetary religion. The BIS was, in fact, his creation. He came on Saturday night and left on Monday night, accompanied by his retinue. The other governors invariably flocked to his room. He had an unbounded admiration for Schacht (in every respect the opposite of himself) and a thorough dislike for one or two others.[15]

And Norman also had his hat—a beautifully crafted, black silk Homburg with a red silk lining embroidered with a golden bee. When Beyen commented on the detail, Norman quipped, "Oh yes, that's the bee I wear in my bonnet."[16]

In 1939 the BIS board welcomed one of the world's most powerful industrialists: Hermann Schmitz, the CEO of IG Farben—the giant German chemical conglomerate. IG Farben was much more than an ordinary business. It was a virtual parallel state, which would soon evolve into an unprecedented synthesis of finance capital and mass murder. Born out of a merger in the 1920s between Bayer, BASF, Hoechst, Agfa, and other companies, IG Farben was the fourth-largest concern in the world (after US Steel, General Motors, and Standard Oil). It produced pharmaceuticals, chemicals, high explosives, film, plastics, fuel, rayon, paint, pesticides, car tires, poison gases, lightbulbs, aspirin, margarine, detergents, fertilizer, and much more. IG Farben provided the nickel for the engines of the Heinkel and Stuka bombers, the aluminum for their bodies, the magnesium for their wings, and the artificial rubber to hold the windshields together.[17] It refined the fuel, oils, and greases that let the Wehrmacht unleash the Blitzkrieg. The firm once attacked by the Nazis as "Isadore G. Farber"—a macabre reference to the former presence of prominent Jewish financiers such as Max Warburg on its supervisory board—was now the centerpiece of the Nazi war machine.

IG Farben had a liaison office with the Wehrmacht to plan its takeover of competitors in newly occupied countries. It ran its own intelligence service, known as "Buro IG," from its headquarters on the Unter den Linden in Berlin. During the war, IG Farben managers built and ran the company's private concentration camp at Auschwitz, known as "IG Auschwitz," which manufactured Buna, or synthetic rubber.

The presence of Hermann Schmitz on the BIS board highlighted how deeply the bank was entangled with the Third Reich. Nazi Germany benefited immeasurably from its relationship with the BIS. By 1939 the BIS's investments in Germany totaled 294 million Swiss gold francs ($96 million), a substantial sum. But the BIS brought much more than money. As the "Young Nazi" quoted at the start of this chapter in Merle Cochran's telegram explained, the BIS gave the Third Reich the chance for a more "normal" type of business relations with foreign countries. It provided the Reichsbank with a ready-made network of contacts and business channels. It gave Schacht, the architect of the German war economy, a regular opportunity to meet his peers and gain intelligence, both financial and political. It legitimized a national bank engaged in state-sponsored financial chicanery, theft, and appropriation of Jewish businesses through state-organized terror. The BIS thus ensured that the Reichsbank, which should have been a pariah institution, remained a central pillar of the global financial system. Schacht's status and prestige and his regular attendance at the Basel meetings made the criminal actions of the Reichsbank seem acceptable. The personal connections of the central bankers, fostered at the BIS's lunches, dinners, cordial receptions, and strolls in the woods, were crucial in this acculturation of Nazi methodology.

The BIS reports during the 1930s and the buildup to war are especially illuminating in this respect—for what they do not discuss, as much as the information they do impart. The bank's access to figures provided by the world's leading central banks allowed it to collate and analyze statistics, to dissect

global trends, and to make policy recommendations in a unique, new format. The BIS annual reports, wrote John Maynard Keynes, the influential British economist, were now "the leading authority for certain statistics, not easily obtainable," and the staff were to be congratulated. The reports were supervised and written by Per Jacobssen, who had joined the bank in 1931 as economic adviser.

Born in 1894, in Tanum, Sweden, Jacobssen had made his name while working at the Economic and Financial Section of the League of Nations from 1920 to 1928. He was far more than an adviser. He shaped the bank's policy recommendations of laissez-faire economics and the importance of individual responsibility over state provision. He supported European federalism and supranationalism. His legacy has shaped our world. Jacobssen was also a kind of global economic troubleshooter with a much-envied contacts book. During his time at the BIS, he oversaw numerous financial and economic inquiries into troubled countries and was especially well connected in the United States. As a perceptive observer, Jacobssen also co-wrote two thrillers, fusing his knowledge of international finance and diplomacy. *The Death of a Diplomat*, which was set in the League of Nations, was published in eight languages, and the film rights sold to a German company. *The Alchemy Murder* was macabrely prescient—especially when Hermann Schmitz, the CEO of IG Farben, joined the board of the BIS. The book's storyline focused on chemical companies producing poison gas.

But Jacobssen's reports for the BIS, no matter how detailed on economic and financial analysis, gave scant attention to the wider context in which the central bankers operated. It was their job, the bankers believed, to focus on finance, rather than on the complex moral and political issues that shaped nations and the world's economy. In this they succeeded so well that an article in the *Bankers' Magazine* in 1943 described the BIS reports as documents "whose emotionless neutrality would do credit to a visitor from Mars." The Nazi persecution of the Jews and the systematic, state-organized theft of Jewish-owned firms and businesses is reported purely as a technical question. Page 101 of the 1939 annual report notes that some German firms had experienced a reduction in liquidity and were asking banks for credit to improve their liquidity. But this was not the only cause of the growth in requests for loans. "Other reasons for the demand for advances are to be found in the changes in the ownership of private enterprises due to the Aryanization of private firms." There is not a word of condemnation, merely a dry noting of the changed circumstances.

The Anschluss, the Nazi annexation of Austria, is noted on pages 100 and 101 of the 1938 report as follows: "In connection with the incorporation of Austria in the German Reich in March and April 1938, the Austrian National Bank entered into liquidation and a series of measures were promulgated transferring most of its assets and liabilities to the Reichsbank." These assets included the Austrian National Bank's gold reserves and their 4,000 BIS shares. The BIS accepted their "transfer" to Berlin, the first of many decisions that the bank's leadership would take to legitimize Nazi plunder and looting.

The BIS's 1939 report does devote more space to the Third Reich's methods, but mainly as a question of technical banking interest. The report notes with typical understatement that "Territorial changes in Europe in 1938 left their impress on the banking and credit structures of the countries concerned." There was perhaps a note of relief in the statement that "the absorption of Austria into the German Reich presented comparatively few difficulties for the German banking system as Austria itself had a unified banking structure." However, the report observed, "much more intricate questions were involved in the taking over of the Sudetenland," the border province that Czechoslovakia had been forced to cede to the Nazis in September 1938. The Czechoslovak banks had 143 branches in the Sudetenland. These banks had to change their currency from crowns to Reichmarks. These 143 branches, the report notes, had to be "severed from their old head offices and adapted to the German system"—an adaptation that the BIS was finding very easy indeed.

The bankers gathered at Basel were not burdened with idealism except in one respect: they wanted to work together to facilitate the free flow of international capital. They sought economic stability, low inflation, and global free trade that would provide political stability and control unemployment—reasonable aims that were shared by much of the world. The bankers may not have been immoral (apart from Schacht), but they were certainly amoral. They believed that financial considerations existed in a vacuum, away from troublesome politics and national interests. Ethical considerations of right and wrong simply did not exist in their universe. What counted was the bottom line and the interest of the banks themselves, especially, now, the BIS. As Merle Cochran noted, "The Directors prefer to view the BIS as a long-term proposition, and insist that its field of usefulness need not be analyzed or altered with every shift in world monetary and economic conditions."[18]

It was a peculiar arrogance that granted such self-belief to a clique of unaccountable financiers. A clique that had, by sleight of hand, built its own bank that was untouchable and beyond the reach of any government—and then proclaimed its existence to be something of virtue for the rest of mankind. The most important thing, the bankers agreed, was that transactions were properly authorized and formal procedures followed. It was not the bank's business to ask where the money came from or how it had arrived. It was this obsessive formalism, repackaged as "neutrality," that would soon lead the BIS to become, in the words of Henry Morgenthau, the US Treasury Secretary, "a symbol of Nazi instrumentality."[19]

TRANSNATIONAL CAPITAL HAD decided the fate of Spain. The Spanish civil war lasted from July 1936 to April 1939, when the Nationalist army, led by General Franco, finally captured Madrid, the capital, from the left-wing Republicans. Spain is often described as a trial run for the Second World War. It was an exceptionally savage conflict, marked by atrocities on both sides. The airplanes of Germany's Condor Legion bombed Spanish cities and strafed civilians, perfecting the strategies that would soon be deployed in the Blitzkrieg. But the conflict was also a trial run for newly honed techniques of economic warfare.

Money, as much as superior numbers and military forces, helped Franco to victory. Nazi Germany and Fascist Italy provided hundreds of millions of dollars worth of aid. The nationalists understood that finance was a weapon as effective as bullets. They set up their own rival economy, complete with a separate national bank that issued its own currency, also called the peseta. This was a psychological as well as economic assault on the Republic. It was chillingly effective. By July 1937, a year into the war, the Republican peseta was worth three times less in French francs than the fascist version, even though the Republicans were the legitimate government of Spain and controlled the national economy, its currency, and the country's gold reserves.[20] Inflation was far higher in the Republican zone. Between July 1936 and March 1937 prices doubled in the Republican zone, while in the nationalist zone they rose by only 15 percent. The nationalists steadily corroded the Spaniards' belief in their currency and, by extension, in their government.

Yet arguably, the Republican government's peseta should have been worth three times the nationalists' scrip. At the end of 1935 Spain had the fifth-largest gold reserves in the world, after the United States, France, Britain, and the Soviet Union. The BIS annual report for 1936 notes that Spain had gold reserves of 2,225 million gold Swiss francs, nearly three times that of Italy. Much of this had been accumulated during the First World War when Spain remained neutral. For the previous four years the country had enjoyed a current account surplus, much of which had been invested in gold.

The country should have been in a prime position to issue bonds, backed by the abundant gold reserves, to finance the economy and the war. Yet as Pablo Martín-Aceña, Elena Martínez Ruiz and

María A. Pons, the authors of the paper "War and Economics: Spanish Civil War Finances Revisited," note the Spanish government did not do so. "The reasons for this decision are controversial: either they were not able to do so because of the political aversion of international banks and financiers, or it was a deliberate policy decision."[21] Probably it was a mix of both. The country was under an arms embargo. And where would the bonds have been sold? Allen Dulles and his friends on Wall Street had no desire to buttress a government that—from their perspective—was composed of dangerous leftists. Nor would London have been more enthusiastic. Britain also preferred Franco's fascists to the Republic.

So Spain simply sold its gold reserves. France bought 175 tons and the remainder was purchased by Moscow. The BIS report for 1937 records a fall in Spain's holdings to an estimated value of 1,600 million gold Swiss francs.[22] The money was used to pay for weapons, aircraft, tanks, food, and other supplies. As neither Spain nor the Soviet Union were members of the BIS, they were not able to use its special facilities for crediting and debiting national banks' accounts. Instead the gold was physically moved. Spain's gold reserves were held in the subterranean vaults of the Bank of Madrid. As Franco's forces advanced on the capital the reserves were transferred to a naval store in Cartagena, on the Mediterranean coast. From there the reserves were loaded onto four Soviet ships and taken to the port of Odessa, to be transported to Moscow on a special train. When the gold was gone, the Bank of Spain sold its silver reserves of 1,225 tons to the United States and France.

The Republicans' chaotic politics also weakened their economy and currency. The nationalists were centralized, authoritarian, well-organized, and united around one ideology—fascism—with one leader: General Francisco Franco. The Republicans were a kaleidoscope of competing creeds: socialism, communism, and anarchism. Numerous local, regional, and revolutionary authorities printed their own banknotes, which had no credible backing. The Republican government did not centralize the issuing of bank notes until autumn 1937. In contrast, the nationalists fought a currency war as well organized as their military campaigns. They declared all Republican banknotes issued since 1936 to be illegal. The only legal tender was to be the notes issued by the nationalists' own rival Bank of Spain. The Republicans blocked all current and deposit accounts in their zone that had been opened or increased in value since the start of the war. So as Franco's troops advanced, bank account holders cashed in their savings and quickly spent the money on whatever they could. One bank, Banco Zaragozano, even sent its chairman to the front. As soon as each city fell, he entered the newly captured territories with the military leaders to reorganize the local banks.[23]

This, as much as the Blitzkrieg, was the real lesson of the Spanish Civil War: the nationalists' sophisticated fusion of financial and military power. The Nazis would hone this model, using the BIS to underpin their economic empire.

"The Bank for International Settlements is the bank which sanctions the most notorious outrage of this generation—the rape of Czechoslovakia."

— George Strauss, Labor MP, speaking in the House of Commons, May 1939[1]

When Nazi Germany annexed the Czechoslovak border province of the Sudetenland in September 1938, it immediately absorbed a good part of the country's banking system as well as most of Czechoslovakia's strategic defenses. By then the country's national bank had prudently transferred most of its gold abroad to two accounts at the Bank of England: one in the name of the BIS, and one in the name of the National Bank of Czechoslovakia itself. (Countries had deposited some of their gold reserves in a sub-account at the BIS account in London to ease gold sales and purchases.) Of the 94,772 kilograms of gold, only 6,337 kilograms remained in Prague. The security of the national gold was more than a monetary issue. The Czechoslovak reserves, like those of Republican Spain, were an expression of nationhood. Carved out of the remains of the Austro-Hungarian Empire in 1918, the Czechoslovak Republic was a new and fragile nation. A good part of the gold had been donated by the public in the country's early years. Josef Malik, the governor of the national bank, and his fellow Czechs believed that, even as the Nazis' dismembered their homeland, if the national gold was safe, then something of the country's independence would endure.

They were wrong. The Czechoslovaks' faith in the probity of the BIS and the Bank of England was tragically misplaced. The gold was sacrificed, with barely a second thought, to the needs of transnational finance and the Third Reich.

The Nazis' first demand came in February 1939 when Berlin ordered Prague to transfer just over 14.5 metric tons of gold, supposedly to back the German currency now circulating in the Sudetenland. This was certainly an innovative idea—first invade a neighboring country, annex part of it, and then demand that the newly truncated state supply the gold to pay for the loss of its territory. The following month the question became academic. On March 15 the Wehrmacht marched into Prague. The German protectorate of Bohemia and Moravia was declared, and Czechoslovakia no longer existed. But the gold reserves did. Three days later a Reichsbank official was dispatched to the National Bank of Czechoslovakia and ordered the directors, under the threat of death, to issue two orders. Thanks to diligent detective work by Piet Clements, the BIS archivist, we have a clear picture of what happened next. The first order instructed the BIS to transfer the 23.1 metric tons of Czechoslovak gold held at the BIS account at the Bank of England to the Reichsbank BIS account, also held at the Bank of England. The second order instructed the Bank of England to transfer almost 27 metric tons of gold held in the National Bank of Czechoslovakia's own account to the BIS's gold account at the Bank of England.

Malik and his fellow directors hoped that it would be obvious that the instructions had been issued under duress and so would not be implemented. The Nazis had just invaded Czechoslovakia and would obviously target the national gold reserves. But Malik had not reckoned on Montagu Norman. The governor of the Bank of England had no interest in whether Czechoslovakia was free or a Nazi colony. "Political" considerations must not affect the BIS's transactions. The transfer order, he said, must go through.

Meanwhile, in Basel, Johan Beyen, the Dutch president of the BIS, wavered. Beyen discussed the matter with the BIS's legal adviser, Felix Weiser. But like Norman, Weiser took the most formalistic approach possible. As long as the paperwork was in order, the monies must go through. Weiser argued, somewhat bizarrely, that there could be no legal grounds to claim that the transfer order had been issued under duress, as such a plea could be brought before a Swiss court only by the persons who had acted under duress. Clearly, the directors of the National Bank of Czechoslovakia were unlikely to travel to Switzerland to present their case. Therefore any decision not to authorize the transfer would be one of BIS policy, rather than administration. The board of the BIS made policy. Thus Beyen would have to consult the board to stop the payment. (This was poor advice for another reason—under the terms of the BIS statutes the Swiss authorities anyway had no jurisdiction over gold transfers between states.)

Beyen was unwilling to take a decision without authorization. But who could he ask? The chairman of the BIS board, Sir Otto Niemeyer, of the Bank of England, was traveling to Egypt and so was incommunicado. At 6 p.m. on March 20, Roger Auboin, the bank's general manager, told Beyen that the governor of the Bank of France had discussed the matter with London. The Bank of England and the Bank of France would not be taking any action to stop the transfer, because they felt that there were no grounds for action. The BIS transfer order went through.

With London, Paris, and Basel's compliance, Nazi Germany had just looted 23.1 metric tons of gold without a shot being fired. More than two-thirds of that gold was traded with the Dutch and Belgian national banks and was eventually transported from Amsterdam and Brussels to the Reichsbank's vaults in Berlin. Czechoslovakia's diligent planning to safeguard its national gold reserves, together with its misplaced faith in the integrity of the new international financial system, had come to nothing. The second transfer order for the 27 metric tons held in the National Bank of Czechoslovakia's own account at the Bank of England did not go through. Sir John Simon, the chancellor of the Exchequer, had instructed banks to block all Czechoslovak assets. But Czechoslovak gold held in a BIS account at the Bank of England, it seemed, was not defined as a national asset and was beyond the reach of UK laws.

Norman and Beyen's decision caused despair and incomprehension in Prague and uproar in London. The loss of the Czechoslovak gold was all "Norman's fault," exclaimed the *Daily Herald*.[2] Paul Einzig, of the *Financial News*, ran a stream of stories exposing the complicity of both the treasury and the Bank of England in the affair. Einzig demanded to know why the treasury had not stopped the transfer, as it was in clear violation of the law known as the Czechoslovakia Act. Brendan Bracken, a journalist and ally of Winston Churchill, declared in the House of Commons that "the Bank of England after what has happened may no longer be looked on as the safest place in the world and the phrase 'Safe as the Bank of England' may no longer apply."[3] Churchill himself demanded to know how the government could urge people to enlist in the military when it was "so butter-fingered that six million pounds of gold can be transferred to the Nazi government."[4]

The real villain of the affair was Norman. Beyen, who later served as Dutch foreign minister and as executive director of the International Monetary Fund, was an ineffectual bureaucrat, paralyzed by the idea that he might have to take responsibility for a decision. Norman could have stopped the transfer immediately. He was the governor of the Bank of England, which held the two BIS accounts involved. At the very least he could have asked for the transfer to be referred to the BIS board for a decision, which would also have been a face-saving measure. He chose not to do so. It was clear that war was coming, one that Britain would have to fight. The Nazi invasion of Czechoslovakia had destroyed the last hopes of peace. That country's gold reserves, held in London, were now a British national security issue.

Yet Norman's priority was not the best interests of his homeland, but rather the independence of his beloved BIS. Even as the shells were loaded into the German tanks, Norman still believed that for the

bankers it could be business as usual. Nothing could interfere with the bankers' sacred neutrality and gentlemanly trust in one other, not even the coming conflagration with a regime whose evil was now plain to see. The Bank of France had refused to stop the transfer but had also asked Norman to block it. Norman was adamant. There could be no political interference in the operations of the BIS, even, it seemed, when they were ordered at gunpoint.

Norman did not express any regret at all over the Czech gold transfer. In fact, he was positively indignant at the very idea that the British government might have some say in the bank's actions. He wrote, "I can't imagine any step more improper than to bring government into the current banking affairs of the BIS. I guess it would mean ruin. I imagine the Germans would never have paid any interest to the BIS, and at the board we would have then likely have found the Germans, Italians, and Japs standing together!"[5] Norman then lied to Sir John Simon, the chancellor of the Exchequer, albeit with a very telling falsehood. Simon asked Norman if he could not have warned the government that, thanks to the BIS, Germany was about to acquire "large additional financial strength." Norman told Simon that while the Bank of England held gold for the BIS, it did not know if the gold was actually owned by the BIS or was held by the BIS for other central banks. This was untrue, as Norman later admitted. Norman then made a significant, even shocking, admission. He told Simon that "he was very doubtful that he would have thought it his duty, as Director of the BIS, to make a statement about its transactions to the British government."[6]

Norman even wrote to Beyen to clarify the matter and to assure the BIS president where his ultimate loyalties lay in Basel. Norman did not want to publicly correct the minutiae of what was being reported in the press and *Hansard*, the British parliamentary journal—that the Bank of England did not know whose gold was held in the BIS accounts—as that would expose him. "The difficulty is that if I point out to the Treasury that this is incorrect, I lay myself open to being asked details of BIS transactions, which I do not consider the Treasury are entitled to know."[7] This was little short of treason. As Norman's compatriots were enlisting in the military, preparing to risk their lives for the freedoms and luxury that he enjoyed, as his country prepared for the war against the Nazis that all knew was coming, Norman blithely announced that his primary loyalty was not to Britain, but to a hyper-privileged, international bank that was not even a decade old.

The mistake of Malik, the director of the National Bank of Czechoslovakia, was to believe that either Norman, Beyen, or indeed any of the BIS management could conceive of any moral or political dimension to their decisions. The world's most powerful international bankers were not only unwilling to obstruct the Nazi seizure of Czechoslovak—or Austrian—assets. They simply could not conceive of any reason why they should do so. As long as the formalities were observed, the necessary papers were stamped and the gold was re-assigned. Norman's precious independence for both the Bank of England and the BIS had been bought at a high price—in mountains of gold ingots to pay for steel to build bombs that would soon rain down on London.

THE SAME OBSESSIVE legalism governed the response of the US Federal Reserve to requests from American banks to transfer Czechoslovak assets. On March 16, 1939, the day after German tanks rolled into Prague, Henry Morgenthau, the US Treasury secretary, called George Harrison, the president of the New York Federal Reserve, to say that the principal banks in New York had been asked—voluntarily—not to make any "important or unusual" transactions involving Czechoslovak assets until Monday, March 20, when the situation might become clearer.

By Tuesday, March 21, the situation was as clear as Bohemia's famed crystal: Czechoslovakia no longer existed. The country had been absorbed into the Third Reich. Harrison called Morgenthau to find out what the US position was. Morgenthau consulted the State Department and told Harrison that the banks

and the lawyers should decide for themselves what to do if they were asked to move Czechoslovak funds. On Thursday, John Wesley Hanes, Morgenthau's undersecretary, called Harrison and asked him to inquire from the New York banks about the deposits they held for the Czech National Bank. The information would be passed to the State Department, which would give it in turn to the Czechoslovak ambassador. Harrison did not agree with the banks' handing over the information voluntarily. That would not be a good idea, as it might trigger retaliation in Germany against American interests. The treasury should compel the banks to surrender the information rather than request it. And if the Czechoslovak ambassador wanted the information, he could look it up himself, in Thomas Skinner's *Bankers' Almanac and Yearbook*.[8]

A few days later, on April 1, the New York Federal Reserve received a cable that ordered the transfer of $35,000 from the Czechoslovak National Bank account into the BIS. Harrison wrote Marriner Eccles, the chairman of the Federal Reserve Board, in Washington, DC, and set out the chain of events. The request, he wrote, was "properly tested in every way." For most observers, the simplest test showed that as Czechoslovakia no longer existed, it was obvious that the request should be blocked. But not to Harrison and Eccles. For them, like Norman in London and Beyen in Basel, the most important thing was to keep the money moving. Harrison could see "no reason, regardless of the possible motive for the transfer, for refusing to honor it." Even worse, was the possibility that there "might be greater liability on us for refusing to honor the transfer than in honoring the order."[9]

The Czechoslovak ambassador thought otherwise. He wrote a letter pointing out that the transfer requests may have been made under duress and asked that such requests not be honored. Ever the bureaucrat, Harrison made sure to guard his back. Just as Beyen had done in Basel, Harrison consulted a lawyer on how to proceed further. The crucial issue was not the Nazi takeover of Czechoslovakia, but the potential risk to the New York Federal Reserve. All drafts against the account of the Czech National Bank's account were to be honored, provided they were properly drawn and tested. "It is our opinion that there is less risk to the bank in following this procedure than in refusing to honor a draft merely because, as the Czechoslovak minister says, it might or might not have been drawn 'under duress.'"[10]

UNUSED TO PUBLIC scrutiny of their decisions, the BIS bankers were taken aback by the depth of the anger against them over the Czechoslovak gold affair. There were recriminations and buck-passing at the BIS board meeting in June that year. Fournier, the governor of the Bank of France, protested that the decision had been taken without consulting the board—which was rich, considering that he had told Beyen that neither the Bank of France nor the Bank of England had any objections to the transfer. Sir Otto Niemeyer, the chairman of the BIS board, defended himself, falling back on the usual excuses. "The Bank had satisfied itself that there was no legal reason why the instructions should not be executed, and the transaction was therefore carried out in the usual manner. There had, in fact, been no alternative but to carry out the instructions received."[11] One director (unnamed) suggested that in future the board should be consulted on "important matters," as the board was responsible for policy. Niemeyer quickly shot down the proposal. Not surprisingly, Niemeyer wholeheartedly took Norman's position. As the BIS was an international institution, it could not concern itself with "political questions." This was nonsense, for the decision to authorize the transfer was profoundly political, executed in a Europe that had never been more politicized and which was about to erupt in war.

Malik left Prague in August 1939 and fled first to Basel, to explain the facts of the Czechoslovak gold transfer to the BIS management before eventually finding refuge in London. There remained the question of the Czechoslovak National Bank's four thousand shares in the BIS. By the end of that year their status, the bank's 1939 report noted, had not still "yet been determined." After the war ended, Malik claimed that

he had to dissuade Paul Hechler, the German head of the BIS banking department and Nazi loyalist, from distributing the Czechoslovak BIS shares to the Reichsbank, the Hungarian National Bank, and the national bank of the new Slovak Nazi puppet state (the banks of the three states that now controlled the former Czechoslovak territories). The "plan was then contemplated by him in all seriousness," Malik wrote.[12] In the end, the BIS took a more judicious approach to the Czechoslovak BIS shares than it had toward the country's gold reserves. After seeking legal advice, the BIS suspended them.

But the affair had highlighted the deeply unsettling connections between the Bank of England, the British government, and the BIS. There was a good deal of cross-party feeling in Britain, reported the *New York Times* , that "the Bank for International Settlements should be liquidated before it furnished any more sinews of war to Germany, and that the odd relationship between the British government and the Bank of England should be re-examined without delay."[13] The *New York Times* then was able to assume that its readers would understand a classical allusion. The word "sinews" was a reference to an epithet of Cicero, the Roman philosopher, who had said, "The sinews of war are infinite money." Cicero's observation was as prescient then as during the late 1930s. But those who wanted the BIS to be liquidated were too late. Thanks to the BIS the "sinews of war" and the flow of near-infinite money were about to be immeasurably strengthened.

THE CZECHOSLOVAK GOLD affair also highlighted how the bank's increasingly sophisticated gold operations were growing in reach and importance. The BIS's gold trades were a primitive forerunner of today's globalized economy where vast sums instantly fly back and forth at the touch of a keyboard. The technology available in the 1930s was far more primitive, but the principle of buying and selling assets sight unseen and without taking physical possession is the same. This development of a free gold market between central banks via the BIS was significant. Had all the Czechoslovak gold been held in an account at the Bank of England in the national bank's own name, rather than at a BIS account, it is doubtful that any would have reached the Reichsbank.

The BIS offered central banks a unique service, one unavailable to private companies or individuals who were not allowed to hold accounts there. The BIS held two kinds of gold deposits: bank deposits and earmarked gold. The first was gold deposited there by central banks. In 1936 this accounted for around 14 percent of deposits. (The actual bars of gold were held at the Swiss National Bank in Bern.) The second category was known as "earmarked" gold—gold that was physically held in another bank but that was credited to the BIS's account (as the Czechoslovak gold in London had been).

The BIS held collective gold accounts at the Bank of England and the New York Federal Reserve. These accounts were subdivided into subaccounts for central banks, which owned the gold, although the gold was physically stored in London or New York. Neither the Bank of England nor the New York Fed was supposed to know which central bank owned the sub-accounts held in the name of the BIS, although as Norman's correspondence over the Czechoslovak gold affair shows, they did. So if the Bank of France (sub-account X) wanted to transfer funds to the Bank of Hungary (sub-account Y), the BIS simply instructed the Bank of England to make the necessary deposit from sub-account X to sub-account Y. Earmarked gold, as Toniolo notes, "allowed for cheap and confidential transactions between central banks, as the transfer of property merely entailed a bookkeeping change by the BIS."[14] This was a growth industry for the BIS—in 1935–1936 earmarked gold movements totaled more than 1,121 million Swiss gold francs. By 1938–1939 that sum had increased to more than 1,512 million.

BIS managers and directors were immensely proud of the bank's innovative, new mechanisms for gold and foreign currency trades. But the principle behind earmarked accounts was not nearly as new as they believed. Few, if any, of the BIS directors had ever heard of the island of Yap, in Micronesia. But

centuries ago its inhabitants had invented a similar system, one based on large limestone discs. The discs, known as *fei*, were quarried on a neighboring island and brought back to Yap by boat. The discs, the islanders decided, represented substantial wealth—enough, for example, to pay for a daughter's dowry. But the "currency" was extremely heavy and almost unmovable. So it stayed in its place, and only the ownership changed with the agreement of the buyer and seller. In fact the stone did not even need to be present on the island. The locals' oral tradition tells of one disc that fell off the boat into the sea. Rather like the gold deposits at the BIS accounts in London or New York—or indeed any bank nowadays—the physical existence of the submerged *fei* was taken as a matter of faith. The islanders simply passed the ownership of the submerged disc back and forth—until 1899 when the Germans arrived and colonized the island of Yap.

The islands' new rulers demanded that the inhabitants repair the walkways that linked the different settlements. The locals ignored their orders, and eventually the Germans decided that they must be fined. Painting a large black cross on the most valuable fei and declaring them to be the property of the government exacted the fine. It worked. The islanders quickly fixed the paths, the German officials removed the crosses, and the islanders once again had possession of their capital assets.

To the sophisticated financiers of the twentieth century, such an episode would have seemed charming but irrelevant. But as Milton Friedman later noted, it was very relevant indeed. Neither gold nor stone discs have any inherent value. Their worth is completely arbitrary, the worth that we give them. The painting of the Yap islanders' stone discs had precise parallels in 1932 when the Bank of France decided to sell its dollars. The bank feared that the United States would not adhere to the traditional gold standard at $20.67 for an ounce of gold. It asked the Federal Reserve of New York to use its dollars held there to buy gold. As it was expensive and risky to ship the gold across the Atlantic, the Bank of France asked the New York Fed to simply store the Bank of France's newly acquired gold at its account there. Friedman described what happened next:

> *In response, officials of the Federal Reserve Bank went to their gold vault, put in separate drawers the correct amount of gold ingots and put a label or mark on those drawers indicating that they were the property of the French—for all it matters they could just have done so by marking them "with a cross in black paint" just as the Germans did to the stones.*[15]

This event—or arguably non-event—had serious consequences. The French sale of dollars drove the exchange rate down, while the franc strengthened, even though nothing had actually happened. What was the difference, asked Friedman, between "the Bank of France's belief that it was in a stronger monetary position because of some marks on drawers in a basement more than 3,000 miles away and the Yap islander's conviction that he was rich because of a stone under the water a hundred miles or so away?"[16] Evidently, not very much.

PERHAPS NORMAN AND Schacht sensed, as they traveled together from Berlin to Basel that January 1939, that this would be the last meeting at the BIS they would attend together. By then Schacht realized that he had created a monster. The German war economy and state spending were out of control. If things carried on as they were, Schacht and his fellow Reichsbank board members believed, the country would go bankrupt. On January 7, Hitler received a memo signed by all eight members of the Reichsbank board, including Schacht. Uncontrolled expenditure would soon cause the "national financial structure" to

collapse, the memo warned. “It is our duty to warn against this assault on the currency.”[17]

Two weeks after Hitler received the Reichsbank directors’ memo, Schacht was summoned to the Chancellery in Berlin. Hitler handed him the official notification that he was relieved of his position as president. Most of Schacht’s fellow directors resigned. Walther Funk, who also took his place on the BIS board, replaced Schacht. Funk, a former journalist, was an ardent Nazi and had joined the party in 1931. He was the point man for big business and industrialists, including IG Farben, who used him to channel funds to the Nazis, and was also one of Hitler’s key economic advisers. Funk had replaced Schacht as economics minister in 1937, and as Plenipotentiary for the War Economy in 1938, so his appointment as Reichsbank president surprised nobody. What was a surprise was how Funk’s dissolute personal life had not stalled his steady rise through the highest reaches of the Nazi state. Funk was a scruffy drunkard and homosexually active at a time when gay men were sent to concetration camps.

Schacht retreated home to his villa in the Berlin suburb of Charlottenburg for a while, and then set off in March on a trip to India. In July 1939 he returned to Basel where he had a secret meeting with Montagu Norman. Schacht made a bizarre offer to the British government. Fearing for his life, and less protected by Hitler from his enemies in the SS, who had always envied his power over the economy, Schacht proposed that he go to east Asia to report on the economy for Britain. Norman met with Neville Chamberlain and told the prime minister of his friend’s request. Schacht’s offer was met with some bewilderment, but Frank Ashton-Gwatkin, a foreign office official, was dispatched to Italy. He and Schacht spent three days closeted in a luxury hotel above Ancona. Ashton-Gwatkin recalled, “I listened to Schacht’s odd-sounding scheme, and, allowing for the fact that he was anxious to get as far away from Hitler as possible, I had to confess that I had heard of more promising ventures.” Still, he told Schacht that he would write a report on his proposal and submit it to London.

Schacht then demanded to see what Ashton-Gwatkin had written. The Foreign Office man handed over his notes. Schacht, imperious as ever, informed him, “This won’t do at all.” Schacht rewrote the report and then demanded that the original be destroyed. Ashton-Gwatkin handed over his notes, which Schacht, with great theater, proceeded to set on fire, sheet by sheet and then drop into the toilet. Schacht was less adept as a spy than a banker. The toilet cracked, and water gushed the wet ashes all over the floor. “We spent what seemed to me a long time mopping up the water and fishing for sodden bits of charred paper,” recalled Ashton-Gwatkin. Schacht’s mission never took place.[18]

Just over a month later, on September 1, Germany invaded Poland.

"The business affairs of the bank, which are run on a greatly reduced scale, virtually rest in the hands of Mr. McKittrick, the president of the bank."

— John Gilbert Winant, the US ambassador to Britain, July 1941[1]

Merle Cochran, the American diplomat whom Henry Morgenthau had dubbed the "unofficial ambassador" to the BIS, had some inside information for the treasury secretary. The main business at the "usual Sunday informal and secret meeting" of the bank's governors that May 1939 was the appointment of the next president. Johan Beyen, the hapless Dutch incumbent who had handed over the Czechoslovak gold to the Nazis, was due to retire in 1940. There were three main contenders to succeed him: a Dutchman, a Swede, and an American. "Chances are best for the American, so far," Cochrane reported.[2]

The American was Thomas McKittrick. On the surface McKittrick seemed a curious choice. He was a lawyer by training with no direct experience of central banking. But that mattered little, for war was coming. All sides already agreed that the financial channels must be kept open during the conflict. In that sense, McKittrick was the perfect candidate. He was citizen of both a neutral country—the United States—and of the world's newest hinterland—transnational finance.

McKittrick had worked for Higginson & Company, the British subsidiary of Lee, Higginson & Company—a renowned Boston investment house. The bank no longer exists, thanks in part to McKittrick, but in its heyday it was richer and more prestigious than Goldman Sachs and Lehman Brothers. Born in St. Louis, McKittrick had graduated from Harvard in 1911. He moved to Italy where he worked for the foreign arm of the National City Bank of New York, before joining the US Army in 1918. He was sent to Liverpool, where he was seconded to British military intelligence, to check that there were no spies using the docks to pass in and out of Britain. After the armistice in November, McKittrick was dispatched to France to work with the Allied occupation forces.

He returned to New York in 1919 and started work at Lee, Higginson. McKittrick's foreign experience in Italy and France made him unusual in the more parochial world of American bankers. He was sent to London in 1921 to work for the company's British wing, and was made a partner in charge of foreign operations for both London and New York. Although McKittrick was a lawyer rather than a banker by training, he soon found his way around the City of London and built up an impressive network of contacts with international connections. Much of his time was spent working on German loans and investments, including the Dawes Plan German External Loan of 1924, which had been arranged by John Foster Dulles and Sullivan and Cromwell. McKittrick became a kind of honorary Englishman, regarded in Europe as an envoy from the City, complete with a butler who ironed his copy of *The Times* before he read it. "I was leading the life of an Englishman," he later recalled. "My associates were all British, and toward the end of that time I was frequently spoken to by people who assumed I was British."[3]

McKittrick had come to the BIS in 1931 when he joined the German Credits Arbitration Committee, which adjudicated over any disputes of credits granted to German private banks. The other two members were Marcus Wallenberg, of Sweden's Enskilda Bank and Franz Urbig, the chairman of the Deutsche Bank supervisory board. Wallenberg and his brother, Jacob, were two of the most powerful bankers in Europe. The Wallenberg family enjoyed a network of lucrative connections to bankers in London, Berlin,

and Wall Street. During the Second World War, the Wallenberg brothers would use Enskilda Bank to play both sides, always making sure to harvest enormous profits along the way. Their relative, Raoul, would later save tens of thousands of Hungarian Jews during the Holocaust before disappearing into the Soviet gulag, abandoned by his uncles.

McKittrick had long been a good friend of Allen Dulles, whom he had first met when Dulles was working at the American Legation in Bern and Dulles assisted him with a visa matter. McKittrick well understood that Sullivan and Cromwell offered an entrée in the covert world where politics and diplomacy met transnational finance. In September 1930 McKittrick wrote to a colleague, "We are seriously considering throwing some legal work to Sullivan and Cromwell in order to get benefit of Dulles services in many directions."[4] McKittrick also arranged short-term loans to the German government. McKittrick's German loans were watched appreciatively at the BIS and Sullivan and Cromwell. In October, Gates McGarrah, the BIS president, wrote to John Foster Dulles expressing how glad he was that the "Lee Higginson [German] credit got itself through."[5]

So were McKittrick and his partners at Lee, Higginson. At least something was going right, for the firm had become embroiled in the affairs of one of the greatest swindlers in history, Ivar Kreuger, a Swedish industrialist. Kreuger had built up a fortune—on the simple safety match—that would now be worth billions.

Wall Street had welcomed Kreuger with open arms and checkbooks. Thanks to McKittrick and his colleagues, Kreuger's reputation had preceded him. The London Higginson partners told their American colleagues that Kreuger had already made them a fortune. But it was a fortune built on fraud. Kreuger had constructed a massive Ponzi scheme that demanded a never-ending stream of new investors to pay their predecessors. In 1931 one of the brokers at Lee, Higginson wrote to Kreuger that some of his bank creditors would like more information about the company and how it worked. The broker asked Krueger to explain what he meant by "loans secured by real-estate mortgages," which was an eerie precursor of the bundled mortgages that triggered the subprime meltdown in 2007.

What Kreuger meant was that he could no longer pay his creditors. He frantically tried to arrange a bailout with Sosthenes Behn of ITT. Behn wrote a check for $11 million on the condition that Price Waterhouse, the accounting firm, could check Kreuger's finances. It did, and it quickly found a hole of $6 million. Kreuger's empire began to collapse. ITT wanted its money back. Kreuger returned to Europe in March 1932 to meet his bankers, but he made it only as far as his apartment on Avenue Victor Emmanuel III in Paris. There, according to most accounts, he lay down on his bed and shot himself in the heart. Lee, Higginson, the venerable Boston bankers who had backed Kreuger for a decade, went bust. The partners were ruined. "I suddenly knew we had all been idiots," an anonymous source told investigators. But McKittrick kept his job at the bank's London branch, as well as his position as vice chairman of the BIS's German Credits Arbitration Committee. It seems there were no recriminations or questions in Basel about McKittrick's judgment—or lack of. McKittrick himself later claimed that he had been selected as president of the BIS without his knowledge or participation. In March 1939, he recalled, "People began whispering—primarily on the continent—'we hear that you're going to BIS as president.' And that continued. The normal grapevine operation." The following month Charles Dalziel, McKittrick's fellow partner at Higginson & Co., told him that "he had heard on an unquestionable basis that I was going to be offered the presidency in the BIS and he wanted me to know that I would make a great mistake if I didn't accept it."[6] Sir Otto Niemeyer, the chairman of the BIS board, made the formal offer in May. McKittrick readily accepted. At first the State Department refused to allow McKittrick to travel to Europe, but after what McKittrick later described as the "principal European countries," doubtless including Britain, applied sufficient pressure, he was allowed to leave. McKittrick moved to Basel and started work in

January 1940 on an annual salary of SF175,000 (US$40,000). He immediately traveled to Berlin, Rome, London, and Paris to meet the German, Italian, British, and French BIS directors and central bankers.

But before McKittrick moved from London to Basel he had another task: to help Hitler's former propaganda chief get released from a British prison camp. In October 1939 Ernst Hanfstaengel's lawyers asked McKittrick to provide a character reference for their client. Hanfstaengel, a Harvard graduate, had lived in New York and was well connected in American high society. He returned to Germany to become one of Hitler's earliest backers. Hanfstaengel lent the Nazi party $1,000 dollars during its early years—an enormous sum during the Weimar hyperinflation—which paid for the publication of the *Völkischer Beobachter*, the party newspaper. Appointed foreign press chief in 1931, Hanfstaengel's job was to present a moderate, sophisticated face to journalists. However his eccentric mannerisms, dry sense of humor, and close connection to Hitler made him enemies, and he fled in 1937. Hanfstaengel's detention as an enemy alien was especially badly timed, explained his lawyers, as he had just signed a contract with an American magazine to write a series of articles about his relations with Hitler—at one dollar a word. McKittrick replied that he would do all he could. McKittrick was ready to declare that the former Nazi spin doctor would not act against British interests if he were set free—although it is unclear how McKittrick could know this.[7] Hanfstaengel was duly released and returned to the United States, where he compiled psychological profiles of Nazi leaders for American intelligence.

McKittrick was not a Nazi, but he was certainly a friend of the new Germany and, like many in his social and business circles at that time, had an ambivalent attitude toward Jews. In November 1938, two weeks after Kristallnacht, he used his contacts to help Rabbi Israel Mattuck, of the Liberal Jewish Synagogue in London. McKittrick introduced Rabbi Mattuck to the US Consul General in London to try and help arrange the immigration of German Jews. Mattuck wrote a grateful note thanking McKittrick "most heartily." The meeting had been very useful. "As a result, I hope that I may, by means of a fund that we have here, help at any rate a few German Jews to find a way of escape."[8] Later on, during the war, in August 1942, Paul Dreyfus, a Basel banker, asked McKittrick to write a letter of introduction to Leland Harrison, the American ambassador to Switzerland. McKittrick obliged but made his feelings about Dreyfus clear in a separate letter to Harrison. "He is, as you will surmise, a Jew, but a good sort who is doing everything he can to help his unfortunate countrymen."[9]

THE OUTBREAK OF war brought existential choices for the BIS's management. There were three options: liquidate the bank, downsize and become dormant until the end of hostilities, or remain as active as possible within the bounds of the declared policy of "neutrality." The directors were unanimous—and already thinking ahead of the needs of transnational capital: the BIS must be kept going to assist with postwar financial reconstruction. McKittrick gave an undertaking to the Swiss authorities that all staff would not "undertake political activities of any sort whatsoever on behalf of any governments or national organizations." Any such departures, he noted in a memo to staff, would be "particularly regrettable at present when special privileges are being sought on behalf of the bank and its staff."[10] A safe passage home would be arranged for anyone who wanted to leave.

The BIS declaration of neutrality meant the following: the bank would not grant credit to central banks of belligerent countries; it would, when operating on neutral markets, ensure that belligerents did not profit from such operations; it would not carry out any transactions, either direct or indirect, between countries at war with each other; it would not sell assets in one country to make a payment to another if they are at war, and it would not hold assets of one belligerent country secured against another. Badly burned by the Czechoslovak gold affair, the BIS said it would not make decisions implying recognition of what it delicately called "territorial changes not universally accepted." When the central bank of the

German Protectorate of Bohemia and Moravia (the illegitimate Nazi regime ruling Czechoslovakia) requested the transfer of its remaining gold held at the BIS to the Reichsbank, it was blocked. When the Belgian government in exile proclaimed that the National Bank's official seat was in London, the Nazi occupation regime responded that the bank's headquarters were in Brussels. The BIS said it was neutral and would not recognize either. The Belgian vote on the board of directors remained unused. The BIS took the same position with regard to Yugoslavia, when faced with competing claims from Belgrade and London.

The bank's declarations of neutrality soon proved worthless. McKittrick and the rest of the bank's management turned the BIS into a de facto arm of the Reichsbank. This was not a result of inertia, passivity, or bureaucratic sloth. It followed from a series of deliberate policy decisions. The BIS carried out foreign exchange deals with the Reichsbank. It accepted looted Nazi gold until the final days of the war, when even neutral countries such as Sweden had begun to refuse it. It recognized the forcible incorporation of occupied countries, including France, Belgium, Greece, and the Netherlands, into the Third Reich. By doing so, it also legitimized the role of the Nazi-controlled national banks in the occupied countries in appropriating Jewish-owned assets. The BIS allowed the Nazi occupation regimes to take ownership of BIS shares, so that the Axis block held 67.4 percent of the bank's voting stock. Board meetings were suspended, but Annual General Meetings continued. Shareholder banks voted by proxy. The case of Poland is telling. In April 1940, Leon Baranski, the Polish representative to the BIS, asked for the government in exile in London to take control of the Polish shares. McKittrick refused. He told Baranski that he did not want to have to issue a ruling, but if he was forced to, the "result may necessarily be an adverse decision" for Poland. McKittrick was determined to avoid raising "a question of this sort," for "once political discussion gets underway, even without publicity, one never knows where it will end."[11]

While Nazi territorial annexations were accepted, Soviet ones were not. In June 1940 the Red Army invaded Latvia, Lithuania, and Estonia. The Soviets ordered the three central bank governors to instruct the BIS to transfer their gold reserves to the Soviet Union's state bank. The parallel with the Czechoslovak gold was clear—but the outcome was very different. The BIS's management, as legalistic as ever, argued that the bank had to accept the instructions. But this time the president refused. "I had to fight my whole management—particularly my legal adviser, saying that we had to accept these instructions and turn the gold over to the Russians. But I just couldn't do it," McKittrick recalled.[12]

Instead, McKittrick commissioned an outside legal opinion from Professor Dieter Schindler of Zürich University. Schindler argued that neither the governors nor the banks of the Baltic States were free agents, but had probably acted under the instructions of the Soviets. He quoted Article 10 of the BIS charter, which prohibited coercive measures against depositors. Thus, Schindler argued, it was the duty of the BIS management to "resist, as far as lies in their power" any attempts by governments to interfere with the BIS's assets. McKittrick was vindicated. He sent a copy of Schindler's memo, which was accepted by the bank management, to Merle Cochran. The BIS president asked him to keep Schindler's legal opinion confidential. "My one serious concern is that it should not get into the press. After the damaging campaign of publicity regarding the Czech gold, it is of the greatest importance to the BIS to remain in the background at this time."[13]

UNTIL THE OUTBREAK of war, the BIS was a congenial place to work. The staff were well paid, intelligent, and cosmopolitan in their outlook. The BIS, like the League of Nations, was an international oasis. Managers regularly traveled to meet their counterparts in London, Paris, Berlin, and other capitals.

The governors' meetings were the high point. Some of the most powerful people in the world traveled to Basel, sprinkling the staid BIS with a little stardust. The staff enjoyed the glamour, the sense of being on the inside track, and the social whirl of dinners, receptions, and teas.

That idyll ended with the fall of France in May 1940. Axis-controlled territory now surrounded Basel on two sides where the borders reach almost to the city limits. Bank officials worked to a backdrop of gunfire. The Swiss authorities feared a German invasion and made plans to evacuate the city. Meanwhile, McKittrick's patrons in London were keeping a very close watch on their protégé. The BIS president was in regular contact with Sir Frank Nelson, the British consul in Bern. Nelson, who was an experienced international businessman, later became chief of the Special Operations Executive, the British wartime sabotage organization. One day, around May 20, as tension soared, Nelson called McKittrick at home at 7 a.m. The British diplomat told him, "Things look very bad indeed. They couldn't look worse." Nelson explained that he must be able to reach McKittrick at any time. He told him, "Don't go out without telling somebody where you are going, and don't leave the next place without telling me where you're going."

At 7 p.m. that evening, McKittrick had returned home when Nelson called again. He instructed the BIS president to evacuate all French and British staff from Basel immediately. The Nazi invasion was imminent, expected to commence at any moment. McKittrick returned to the bank's headquarters and summoned his senior staff, including Roger Auboin, Rafaele Pilotti, and Paul Hechler. They contacted as many French and British employees as they could. Hechler then told McKittrick, "You're the only man who alone can dispose of the assets of this bank. I think you're the most important man for us to get out of Basel." McKittrick agreed and quickly abandoned his colleagues. He called his chauffeur, and went home and grabbed some clothes. The chauffeur, McKittrick recalled, "didn't pack them but stuffed them into the car." They headed for Bern and were stopped on route fourteen times by Swiss soldiers or police.[14]

The German invasion of Switzerland never happened. Swiss francs, Swiss banks, and the BIS were far more use to the Third Reich than another stretch of mountainous territory, where a stubborn, hardy population would have likely waged guerilla warfare against the Nazis. The BIS relocated to Château d'Oex, in the southwest of the country. McKittrick and Per Jacobssen moved into the Chateau de Rougemont, kindly loaned by its American owner. The rest of the staff had to make do in the village. There were few decent houses, schooling was basic, and the village was tiny. By the end of the autumn, as the war ground on, relations between the different nationalities were near-poisonous. Morale was collapsing, recalled McKittrick. "There was only one movie house in town, and if a Frenchman and his wife went to the movies, and a German and his wife went to the movies, and they walked into each other, it was an embarrassment for all concerned."[15]

Everyone was relieved when the BIS returned to Basel in October 1940. There, despite the conflict, the BIS continued to enjoy immense financial as well as legal privileges. It could buy and sell unlimited amounts of Swiss francs. This was the most important currency in wartime Europe, accepted everywhere. The BIS, thanks to its charter, did not have to report foreign exchange transactions. Its exchange rate against the Swiss franc was not subject to the same restrictions as Swiss commercial banks. Until 1942 the BIS could buy and sell gold at better rates than the Swiss National Bank. This bizarre setup, where Allied and Axis bankers worked together so profitably, drew increasingly hostile attention in London and Washington, DC.

The State Department asked the American embassy in London to investigate the state of the relationship between the British government and the BIS, noting that "many problems" have come up. John Gilbert Winant, the ambassador, met with Sir Otto Niemeyer, the former chairman of the BIS board. Niemeyer was as adamant as ever about the BIS's immunity. He pointed to article 10 of the BIS's charter that guaranteed that in the event of war, the property and assets of the bank shall be immune from seizure.

Niemeyer had even made arrangements with the British government that BIS communications to London could pass directly through the censor. "It is Niemeyer's belief," wrote Winant, "that the British should continue their association, as well as lend the bank their tacit approval, if only for the reason that a useful role in postwar settlements might later have an effect."[16] While the BIS was operating in such a restricted manner, "it was felt that it would be of no use at this time to raise difficult legal questions with respect to the relationship of the various countries overrun by the Germans." Niemeyer argued that McKittrick should stay in Switzerland as he was "the guardian of the bank against any danger that might occur."[17]

McKittrick was far more than a guardian of the BIS. He repeatedly passed economic and financial intelligence to the Reichsbank leadership. McKittrick was especially close to Emil Puhl, the vice president of the Reichsbank and BIS board member, whom McKittrick described as his "friend." Puhl, a gold and currency specialist, was a regular visitor to both the BIS at Basel and the Swiss National Bank in Bern. He had close links with the financial wing of the SS that managed its extensive business interests. Puhl, rather than Walther Funk, his nominal superior, was the real boss of the Reichsbank. In autumn 1941 McKittrick gave Puhl a tutorial on the Lend Lease program, under which the United States supplied the Allies with arms, ammunition and other war material. The act, passed in March of that year, effectively marked the end of the United States' policy of neutrality. McKittrick later recalled the conversation. Puhl asked the BIS president,

> *"What does this Lend Lease thing mean? We don't understand it. Is there anything you'd be willing to tell me about it?" And I [McKittrick] said, "Yes. I'll give you this. It's my own idea but there's no reason I shouldn't tell it to you. I think that if America is going to be in the war something will happen to get us in. Just the way it did in the first war. And what is happening is that we're getting our industrial organization into shape for our entry into the war." I've never seen a man's face drop more than his did. I though he was going to faint or something. He said, "My God. If you're right, we've lost the war."*[18]

McKittrick's prediction proved correct. But America's entrance into the war in December 1941 caused him further problems. The BIS president was no longer a neutral, but a citizen of a belligerent nation—in daily contact with his German, French, and Italian colleagues. But the advent of hostilities between the United States and Nazi Germany did not change his cordial and productive relationship with the Reichsbank. Puhl wrote of McKittrick in September 1942, "Neither his personality nor his manner of conducting business have been any cause for any criticism whatsoever."[19] Puhl even described the BIS as the "only real foreign branch" of the Reichsbank.[20] Some of the BIS dividend payments to its shareholders in Nazi-occupied countries went through the Reichsbank, thus giving Berlin access to the foreign exchange transactions and allowing it to charge a fee for its services. During the war the Reichsbank continued to pay interest on BIS investments in Germany, even though that interest contributed to the bank's dividends, which were paid to its shareholders, including the Bank of England. Thus, through the BIS, Nazi Germany was contributing to Britain's wartime economy.

It was a price worth paying, Puhl believed. For despite Hitler's bluster and Schacht's planning, Nazi Germany had not achieved autarky. It needed to buy vast amounts of raw materials to manufacture armaments and to feed, heat, and clothe its population. Swedish steel, Romanian oil, Portuguese tungsten, even South American beef, all had to be purchased and paid for in hard currency. Nazi Germany needed a financial channel to the neutral countries it ran through Basel. Which is the main reason why Nazi Germany did not invade Switzerland or Sweden. These neutral countries were far more use to the Third

Reich as monetary hubs on the transnational financial network than as extra swathes of German-controlled territory.[21]

When questions were raised at the German Foreign Ministry as to why the Reichsbank remained a member of a bank with an American president, Puhl was the BIS's most influential advocate. The BIS was one of Germany's most important external trading partners, he argued. It carried out gold and foreign exchange transactions and gave the Reichsbank a mechanism for buying vital war materials. It was a listening post, providing useful intelligence on enemy financial transactions. The Germans working there, such as Paul Hechler, the assistant general manager, were loyal and efficient. If Germany pulled out and the BIS closed down, it would be an enormous loss to the Nazi war effort. And the BIS needed the Reichsbank—and Puhl—just as much. Per Jacobssen, the BIS's economic adviser, had lunch with Puhl on December 7, 1942, at Puhl's office in the Reichsbank. The two men always enjoyed each other's company. They had a pleasant meal, just a short walk from the bank's vaults that held the wealth of a looted continent and of its exterminated Jews. Puhl, Jacobssen believed, was the BIS's most important ally in Nazi Germany. Without his support the bank would collapse. Jacobssen later wrote in his diary, "I know full well to what extent the future of the BIS depends on Puhl's possibilities of holding the fort in Berlin."[22]

THE WAR WAS not good for the BIS's balance sheet. By 1943, its business volume fell to less than 5 percent of the average for prewar years. But the BIS had 294 million Swiss gold francs ($96 million) invested in Germany in the form of state bank funds, bills, and bonds. The bank was kept going by the interest payments it received from the Reichsbank, which eventually accounted for 82 percent of its income. At first Germany paid its dues in currency. But after March 1940 it changed to gold, much of it looted. During the war Germany added $603.5 million worth of gold to its reserves, more than 80 percent of which was plundered from the central banks of occupied countries. $88 million-worth was seized from citizens of Germany and Nazi-occupied territories. Around $3 million worth was taken from concentration camp victims, including the macabre category of "dental gold." This was also credited to an account at the Reichsbank, overseen by Emil Puhl, the confidant of Thomas McKittrick and lunch partner of Per Jacobssen.[23]

Thanks to research by Piet Clements, we know that during the war years a total of 21.5 metric tons of gold passed in and out of the Reichsbank gold account at BIS, of which 13.5 metric tons was acquired during the war. Some of the new gold—much of which was looted—was used to pay the interest on the BIS's loans and investments to Germany. Six metric tons were used to pay the Reichsbank's debts through the BIS payments system for international railway and postal traffic, which the bank also handled.

The fate of the Belgian gold reserves is the most extraordinary. At the end of 1939 the National Bank of Belgium sent more than 200 metric tons of its reserves to France for safekeeping. As the Nazis advanced, France transported the Belgian gold and some of its own to the port of Dakar in West Africa. Fearing an Allied raid, the French authorities then moved the gold inland. After the fall of Paris, Germany ordered the collaborationist French government based in Vichy to send the gold to Marseilles to be taken into the "custody" of the Reichsbank. The gold was then transported by boat, truck, train, and camel train through the Sahara Desert to Algiers. From there it was flown to Marseilles and eventually deposited in the vaults of the Reichsbank.

In the summer of 1943 Yves Bréart de Boisanger, the governor of the Bank of France, now under Vichy control, traveled to Basel to warn McKittrick about the fate of the Belgian gold, some of which would doubtless end up in Basel. McKittrick dismissed de Boisanger's concerns. All the gold received at the BIS had been stamped with the proper markings, he said, and was German, not Belgium. Whether or

not he believed this, McKittrick understood that if the bank were to stay in business there was probably no other option than to accept the Reichsbank's gold shipments. But Auboin, the French manager, sided with his compatriot. The BIS should no longer accept German payments in gold, but demand Swiss Francs instead.

Auboin was right. The Belgian gold had been melted down at the Prussian Mint and stamped with false identifying numbers and dates between 1934 and 1939. About 1.6 metric tons was used by the Reichsbank to meet its BIS interest payments, as well as 2 metric tons of looted Dutch gold.

However, not all the gold melted down at the Prussian Mint originated in the vaults of national banks. The Nazis set up a network of informers and torturers, called the Devisenschutzkommando (DSK), to track down private gold holdings in occupied territories. The stated purpose of the special unit that was handpicked by SS soldiers was to control currency traffic across the Third Reich. Its actual purpose was "the acquisition of gold by any means, including deceit and brutality," according to British intelligence records. In Paris alone the DSK employed eighty informers, from the "lowest levels of society to the highest circles."[24] Each received a 10 percent commission, as well as false identity cards and counterfeit American and British currency. Victims were lured with supposed sales of property or land. They were then arrested, beaten, and tortured to reveal how they would pay for such a purchase. The favorite interrogation method of Hugo Doose, who ran the DSK for the Channel Islands, was to break a beer glass over his victim's head. Ludwig Jaretski, an Austrian living in Paris, "employed burning matches on stripped victims."[25] Some of the BIS gold had an even more grisly origin, which came from the watches, spectacles, jewelry, and gold teeth of concentration camp victims. This was why, after the war, Emil Puhl, vice president of the Reichsbank and BIS director, would be found guilty of war crimes.

Under McKittrick's leadership, the BIS also carried out a significant number of gold transactions for other Axis powers. It sold gold for the Bank of France (Vichy) to Portugal for escudos, which France needed to pay for Portuguese imports. It organized three gold shipments from Bern to Bulgaria. It sold almost nine metric tons of gold to Romania, by undercutting the Swiss National Bank. All of these were direct breaches of the policy of neutrality. The BIS also carried out thirteen gold swaps with Turkey—a total of 8.6 metric tons—exchanging gold that Turkey had held at the Swiss National Bank for BIS gold that was held in New York, Paris, and London. Turkey was technically neutral but had strong trade relations with Germany and was the Third Reich's main supplier of chromium. Nor was the BIS was alone in its acceptance of looted Nazi gold, and the failure of its managers to check the gold's provenance. Swiss commercial banks and the Swiss National Bank (SNB) also readily accepted looted Nazi gold. The bankers' policy of "business as usual" with the Nazis was led from the top. Ernst Weber, the chairman of the BIS board from 1942 to 1947, was also the president of the Swiss National Bank. Weber, like McKittrick and Jacobssen, enjoyed cordial relations with Puhl. Even as the Allies fought their way through Nazi-occupied Europe to the Swiss border, Weber and Puhl were still arranging gold shipments. The two bankers had dinner together on December 10, 1944, to discuss their latest arrangement: Switzerland would buy German gold, and in exchange Germany would sell Switzerland coal. The negotiations took place in what Otto Köcher, the head of the German legation in Bern, called the "usual atmosphere of trust."[26]

The cozy relations between the BIS, the SNB and the Third Reich stayed buried until the late 1990s, when the scandal broke that Swiss commercial banks were still holding the assets of Holocaust victims. The BIS and the SNB were soon dragged in. A report commissioned by the Swiss government, published in 1998, said that Swiss National Bank officials followed an "ethic of the least effort" to check the origins of the gold sent to Switzerland, some of which had been looted from Holocaust victims. During the war the SNB bought $280 million of gold from the Nazis. By 1943 the SNB knew about the extermination of

European Jewry, but bank officials did not take measures to distinguish looted gold from other Reichsbank holdings.[27]

DESPITE MCKITTRICK'S SAFE and privileged existence, he was often lonely. His wife and four daughters were far way in the United States. Travel remained difficult and slow. There were few visitors in Bern, apart from Emil Puhl, and the postal service was erratic. McKittrick kept an account at a bookshop on Charing Cross Road and took refuge in non-bankerly works including, *Will Europe Follow Atlantis*, which examined the coming cataclysm of European civilization; a work of Sufi devotion called *At the Gate of Discipleship;* and even *The Occult Causes of the Present War*. McKittrick went walking in the woods and mountains with Erin Jacobssen, the daughter of the bank's economic adviser. A keen botanist, McKittrick taught Jacobssen about the region's rich flora. Other correspondence doubtless cheered the BIS president. Hermann Schmitz, the CEO of IG Farben and BIS board member, for example, sent his sincerest New Year wishes on January 3, 1941. Schmitz wrote, "For their friendly wishes for Christmas and the New Year, and for their good wishes for my 60th birthday, I am sending my sincere thanks. In response, I am sending you my heartfelt wishes for a prosperous year for the Bank for International Settlements."[28] It would certainly be another prosperous year for IG Farben, whose profits were soaring and whose plans were well advanced for the construction of IG Auschwitz, the firm's own corporate concentration camp.

Most of the BIS staff stayed, but Charles Kindelberger, an American with a young wife, returned home. His departure left a vacancy. Leon Fraser, now president of the First National Bank of New York, had a suggestion for his old friend McKittrick. In November 1940, Fraser met with a young man named Henry Tasca in Washington, DC. Tasca was working at the National Defense Commission, specializing in foreign trade and Latin America. "He has a pleasing personality, a manifestly keen mind, and is ambitious and hard-working."[29] Tasca could leave for Switzerland on thirty days' notice. "He makes a much more favorable impression than did Kindelberger, both in appearance and seriousness of purpose."[30] And Tasca, fortunately, had the right answer for the most sensitive question, reported Fraser. Merle Cochran had asked it, "and the reply was that Tasca was not Jewish."[31]

As the war ground on, the Czechoslovak gold affair still haunted the BIS. Once again, there were angry questions in the House of Commons about Britain's continued membership, the bank's role, and its connections to Nazi Germany. The government stayed firm in its support. Sir Kingsley Wood, the finance minister, declared in October 1942 that with McKittrick at the helm, there was nothing to worry about. "The conduct and control of the bank have been and are today in the sole hands of the President of the Bank, an American citizen. . . . This gentleman has our complete confidence."[32]

In Washington the Treasury Department was increasingly hostile, especially after the United States entered the war in December 1941. McKittrick's first term of office ended in December 1942. Many argued that it should not be renewed. Montagu Norman was certainly worried. In June 1942, Norman wrote to McKittrick to assure him of his continuing support. "We certainly hope that means can be found for you to continue your presidency of the Bank, indeed it is not too much to say that we regard it as *essential*."[33] Perhaps McKittrick could simply "carry on without any formal steps at all." Bearing in this mind, it would be helpful for McKittrick to visit the United States. "We would at any rate do our best to make that possible."[34]

Norman and his allies had a plan: to appoint Ernst Weber, the president of the Swiss National Bank and a BIS board member, as chairman, as long as he agreed to re-appoint McKittrick as president. Weber would be a neutral figurehead for the BIS and provide cover for its activities. As Ivar Rooth, the governor

of the Swedish Rijksbank, wrote to Norman, it was "important" that the Bank should be safeguarded by "putting in as authoritative position as possible a personage of neutral nationality."[35] Weber's discretion was guaranteed. In 1940 McKittrick had mentioned the Czechoslovak gold to Weber. The BIS president explained that the conversation went like this: "I asked him not to tell me where the gold would go, and he did not do so."[36] McKittrick was in close contact with Weber, whom he met in Zürich or Bern two or three times a month.

In Berlin, Joachim von Ribbentrop, the former German foreign minister, did not understand McKittrick's value to the Third Reich either. McKittrick should resign, he thought, and be replaced by a neutral, or Germany should sever its links with the BIS. Emil Puhl and Paul Hechler swiftly went into action. Both were great admirers of McKittrick, whom they described as "professional and loyal."[37] They told von Ribbentrop that if McKittrick went, Ernst Weber, once appointed chairman of the board, would take control. Even if McKittrick was deposed as president, the United States would still have a representative in the bank's management. Such a person would undoubtedly disrupt the "until now smooth functioning of the BIS and its use by us for conducting gold and foreign exchange transactions."[38]

McKittrick himself lobbied Marcel Pilet-Golaz, the Swiss foreign minister. The two men met in October 1942. There were several items to discuss. The unpleasant articles about the BIS in the British press unsettled McKittrick. The BIS president was hypersensitive to criticism or any hint that the British government might withdraw its support for the bank. As the bank depended on its neutrality for its continued existence during wartime, a British withdrawal would spell the end. The Swiss legation in London had taken the matter up with the Foreign Office and the Treasury. The articles did not reflect British governmental opinion, Pilet-Golaz said, reassuringly. Pilet-Golaz also confirmed the Swiss government's support for the BIS. The Swiss attitude to the numerous international organizations it hosted "varies very much."[39] He complained the League of Nations was the worst. The conduct of its staff left much to be desired, and it had created "numerous political difficulties."[40] The International Labor Organization (ILO) was somewhat better regarded, while the BIS had never "given cause for severe criticism."[41] It would certainly be a "cause for regret" if the bank would leave Switzerland.[42]

McKittrick then raised the delicate matter of the Weber plan. The chairman of the board, he explained, was very different to being president of the bank. The board dealt mainly with the bank's internal governance. The big questions of transnational capital flows, loans, and currency support were dealt with at the governors' meetings, which were anyway suspended for the war. Pilet-Golaz was agreeable, noted McKittrick. "He thinks it desirable that Switzerland should assist in the maintenance of international organizations and as an intermediary between belligerent countries when this can be done without undue publicity and when it does not interfere with the general policy of neutrality."[43]

It worked. Weber was appointed chairman of the BIS board. And on January 1, 1943 the Swiss banker re-appointed McKittrick for a further three years. By then, the BIS president—just as Norman had suggested—was in the United States.

"He believes that the Germans—at least those connected with the Reichsbank —desire his return [to Basel] and that some way will be found to make it possible."

— American intelligence report on Thomas McKittrick and the BIS, December 14, 1942[1]

The BIS had pioneered swift movements of international capital but could do little to speed its president across the Atlantic with enough cash in his pocket. In late 1942 Thomas McKittrick planned to travel to France, Portugal, Spain, and Britain, and then head to the United States. But even with his privileged status, he was still subject to currency control laws that allowed him to take a maximum of 1,000 French francs into France. "Can French franc banknotes be sent by registered mail to Spain from Switzerland?" he wondered in a note to himself. Such postal smuggling might be a better option, as he could use the French francs to buy pesetas on the black market. "Spanish currency can be obtained on better terms than by exchanging dollars or Swiss francs in Spain at the official rate," McKittrick mused to himself. Food might also be problematic, especially perhaps for someone used to the BIS dining room. "Take sandwiches to supplement food available in France. On arrival in France, ask for bread coupons. Use these to purchase bread on leaving France, as bread in Spain is very scarce and bad."[2]

McKittrick left Basel in early November and arrived in Lisbon some days later. There, while checking into his hotel, he had a pleasant surprise. He recalled, "The first thing I knew, somebody grabbed me from behind and said, 'Is that you Tom McKittrick?' I said, 'Yes' without seeing who it was. He said, 'Well, my gosh, I've got to see you. You're the first man I wanted to see in Switzerland.'" [3] It was Allen Dulles, who was on his way to Bern to set up the Swiss station of the Office for Strategic Services, the embryonic American foreign intelligence service. The two men spent some enjoyable time together before McKittrick flew to London. There he spent two weeks ensconced with Montagu Norman and Sir Otto Niemeyer. McKittrick then traveled to Ireland, took a flying boat back to Lisbon, and eventually reached New York via Portuguese Guinea, Liberia, Brazil, Trinidad, and Puerto Rico.

There was much to think about on the long and arduous journey. The BIS now had a suitably neutral chairman in the shape of Ernst Weber, the president of the Swiss National Bank, and McKittrick had secured himself another three years as president. McKittrick had lobbied hard for a second term, using his extensive network of diplomatic contacts to make sure he was acceptable to both the Allied and Axis powers. The world was at war, but the one thing both sides could agree on, it seemed, was that the BIS should stay in business, with Thomas McKittrick in the president's chair. The American banker carefully cultivated his friends at the foreign legations in Bern. He was so successful that the foreign diplomats even sent his letters in their embassies' diplomatic pouches, McKittrick later recalled. "I made it my business to keep on good terms with their ambassadors or ministers in Bern, and they were all of them kind enough to send letters that were of certain importance and secrecy in the diplomatic pouches—so they were all informed of this and they all agreed to do it."[4]

The American Legation in Bern also encoded communications from the BIS to McKittrick while he was in the United States. In February 1943 Roger Auboin, the BIS's general manager, asked the US

Legation to send a coded cable to McKittrick inquiring about the arrangements for his return journey to Basel, via Lisbon:

> *Please communicate as soon as possible approximate date arrival Lisbon to enable us to settle material details of your journey regarding which we shall cable you in due course care American Legation Lisbon.*[5]

It seemed that Leland Harrison, the American ambassador to Switzerland, even allowed McKittrick to write his cables for him—in exchange for a substantial sum of money. On November 15, 1943, McKittrick wrote to Harrison about "the draft cable of which we spoke on Thursday." The cable had been "recast," noted McKittrick, who admitted he had "gone rather far in putting words" into Harrison's mouth. "My purpose has not been to tell you what to say but to avoid leaving blanks in the picture, and if I have used the wrong color anywhere you will please make the necessary correction." McKittrick then promised Harrison a "reward" for his services, of three million Swiss francs (around US$700,000).[6]

The Treasury Department did not share the State Department's enthusiasm for McKittrick and the BIS. Henry Morgenthau, the Treasury secretary, and his colleague, Harry Dexter White, loathed the BIS, seeing it, correctly, as a channel for the perpetuation of Nazi economic interests in the United States. They ensured that the bank was facing ever more obstacles to doing business in the United States. Under wartime legislation Swiss banks, including the BIS, could operate only under special license in the United States. At first, McKittrick's friends at the New York Federal Reserve had obtained a general license for the BIS, so most routine transactions could be executed without delay. But that was revoked in June 1941, which caused substantial difficulties. The bank's dividends to its American shareholders, and other planned transactions, were blocked. The Treasury Department believed that Swiss banks were being used to transfer ownership of Italian and German firms to Swiss or American front companies. Their investigators were unraveling the links between New York, Berlin, and Bern. For example, Felix Iselin, a Swiss banker, was the chairman of IG Chemie, the Swiss subsidiary of IG Farben, the industrial conglomerate that drove the Nazi war machine and whose chairman, Hermann Schmitz, sat on the BIS board. Iselin also sat on the board of the Swiss Bank Corporation and the Credit Suisse bank.[7] IG Chemie was a holding company for General Aniline and Film, IG Farben's American subsidiary.

Morgenthau was a doughty foe, drawn from a very different world to McKittrick's WASP friends on Wall Street. Born into a prominent Jewish dynasty in New York, Morgenthau was an intellectual and a farmer who grew Christmas trees. His father, Henry Morgenthau Sr., had served as American ambassador to the Ottoman Empire during the Armenian genocide and had loudly condemned the extermination. A close friend of Franklin and Eleanor Roosevelt, Henry Morgenthau had a strong sense of social justice and was a key architect of Roosevelt's New Deal. White, like Morgenthau, was also Jewish, but his parents were poor Lithuanian immigrants. Born in Boston, White worked for a while for his father's hardware business and served in the US Army during the First World War. White was a prize-winning Harvard economist and had a solid understanding of the new global financial architecture emerging under the aegis of the BIS. He left academia to work at the Treasury, where Morgenthau placed him in charge of international affairs. Morgenthau and White would prove to be McKittrick's most powerful enemies in the United States. McKittrick later recalled that White "hated me, because I was doing things that he couldn't get done because I could get in all sorts of places in Europe that he couldn't get his people in."[8] This was largely because many of the things that McKittrick was doing, such as gold and foreign exchange deals with the Reichsbank after Pearl Harbor, were treasonable.

Once McKittrick had safely arrived in Manhattan, he set up an office at the Federal Reserve, with the help of his old friend Leon Fraser, the former BIS president who was now president of the First National Bank of New York. McKittrick needed a lawyer to persuade the Treasury to unblock the BIS's funds. His choice was never in doubt: John Foster Dulles. Meanwhile, McKittrick made the rounds of government departments, trying to show how the BIS could help with the American war effort by offering financial services and helping in the postwar reconstruction of Europe. The BIS president was much in demand as a fresh, firsthand source on wartime Europe. "I had a lot of questioning to go through in Washington, because everybody wanted to know everything about the war in Europe, everything about political affairs in Europe."[9] McKittrick also met Henry Morgenthau. The encounter did not go well. McKittrick laid out his arguments for paying dividends to American BIS shareholders and the bank's position on other contentious matters. Morgenthau walked out after twenty minutes, recommending that he consult Treasury experts.

But the worst was to come. In April 1943, while McKittrick was still in the United States, Congressman Horace Jeremiah Voorhis demanded an investigation into the BIS. Voorhis wanted to know why the bank's president was an American and whether the bank was being used to help the Axis powers. Voorhis, McKittrick believed, was being fed information by Paul Einzig, the BIS's journalistic nemesis, who ever since the fiasco of the Czechoslovak gold, had lambasted the bank in the British financial press. Einzig was a dogged reporter, whose criticisms of the bank struck a nerve, so much so that McKittrick, always hypersensitive about press coverage, referred to him in one letter to Leon Fraser as a "swine."[10]

McKittrick then found he could not get permission from the US authorities to return to Basel. He was stranded, his requests for help unanswered. "I talked to the State Department and they made believe they didn't know what I was talking about."[11] McKittrick asked Col. Bill Donovan, the OSS chief and Allen Dulles's boss, for help. Donovan also stonewalled the BIS president, repeatedly promising him to sort out his passport. But the passport did not arrive. The OSS did not want McKittrick to go anywhere until he had told them everything he knew about Nazi Germany's economy, the Swiss connection, the role of the BIS, the progress of the war, in-fighting among the Nazi leadership, conditions inside Germany, and anything else of interest. McKittrick was called in for several interviews. He was, it turned out, a fantastic source, if somewhat delusional about the centrality of his own role. Even with all that we now know of the BIS's wartime record, the OSS report of McKittrick's explanations of why an American should run an international bank that was under de facto control of the Nazis is still eye opening.

The Weber plan—to install the president of the Swiss National Bank as BIS chairman—McKittrick explained, had been carried out with the full knowledge of the Reichsbank and the German Foreign Office. Both also knew that the Swiss banker would name McKittrick as the next BIS president and were satisfied with that. Hitler himself, though, was not involved, and the plan to extend McKittrick's term as president avoided mentioning the American banker in detail, in case Hitler "heard of the matter" and became angry. The OSS memo reveals how much high-grade economic intelligence McKittrick had access to: the governor of the Hungarian National Bank explained to him how Hungary had deliberately obstructed a new trade agreement with Germany; Vichy France, had been sending gold into Switzerland by a roundabout route to avoid occupied France; Switzerland was awash with Romanian oil, as Romania preferred to sell there rather than to its ally Germany; Walther Funk, the Reichsbank president, had failed to persuade Germany's allies in the Balkans that their debts would eventually be paid. There is an intriguing glimpse into the morale of the BIS's staff: the bank employed fourteen British staff and eight Italians. The Italians were "morose and depressed." They felt that Italy was already defeated and would not "have a friend in the world."

McKittrick's Reichsbank contacts made him an excellent source for news about life inside the Third

Reich. Hitler, McKittrick revealed, had become indecisive. "Instead of having a definite plan laid out, and pursuing it relentlessly, he switches from one plan to another," the OSS document noted.[12] There were even rumors that he had started drinking. Despite the soaring casualties on the Eastern Front, and the surrender at Stalingrad, most Germans, McKittrick explained, still believed state propaganda. He related how one friend of his in the Reichsbank said he had to get out of Germany every now and again or he would start to believe the propaganda himself. McKittrick was also in contact with Hjalmar Schacht. The BIS president was not a fan of Schacht's and regarded him as a "political crook and entirely untrustworthy." Schacht still saw Hitler every couple of months, and when the Nazi leader asked numerous technical questions Schacht proffered his advice. Sometimes Hitler took it, other times not. As for Basel, McKittrick believed that there were twenty thousand Germans living in the city, who were "well-organized under Nazi leadership." He did not believe he was under observation by the Gestapo.

Some of most intriguing material the OSS obtained from McKittrick detailed his role as a back-channel between anti-Nazi Germans and the United States. This doubtless explains why the State Department eventually allowed him to return to Basel and the BIS to stay open. McKittrick told the OSS that he received "peace feelers" from non- or anti-Nazi Germans twice a month. All of them, however, argued that, even if a deal was made, Germany would remain the dominant European power "with a free hand in the east and a large measure of economic control in western Europe." These envoys included a "Berlin lawyer" and a "retired diplomat" Adam von Trott zu Solz. A former Rhodes Scholar at Oxford University, von Trott was a German nobleman and diplomat. He had lived in the United States and was active in the resistance against Hitler. McKittrick's personal papers include the record of a meeting with von Trott in June 1941. Von Trott asked McKittrick to arrange for five hundred dollars to be transferred by the Institute of Pacific Relations (a liberal think tank based in New York) to Switzerland, so von Trott could keep in touch with the IPR's European members. Communications for von Trott should be sent through Werner Karl von Haeften, the German consul in Basel, McKittrick noted.[13] Von Trott was a leading figure in the July 1944 plot against Hitler. Had it succeeded, he would have become foreign minister and led negotiations with the Allies. After it failed, von Trott was hanged.

McKittrick, like his colleagues in London and Berlin, strongly emphasized the BIS's future use in planning the postwar order. "While it does not concern itself with political affairs, it does offer facilities for the discussion of postwar financial and economic questions," wrote the author of the OSS memo, "and he thinks that a year or two can be saved in getting Europe back to work by informal international conversations under its auspices."[14]

McKittrick's return to New York was the talk of Wall Street. On December 17, 1942, Leon Fraser hosted a dinner for him at the University Club. Thirty-seven of the United States' most powerful financiers, industrialists, and businessmen gathered in his honor. The Treasury was stonewalling him, his passport was stuck on a bureaucrat's desk, and the OSS was grilling him, but here at least friends and admirers surrounded him. They included the presidents of the New York Federal Reserve, the National City Bank, the Bankers' Trust, the New York Life Insurance Company, the New York Clearing House Association, and General Electric, as well as a former undersecretary of the Treasury and a former US ambassador to Germany. Standard Oil, General Motors, J. P. Morgan, Brown Brothers Harriman, several major insurance companies, and Kuhn Loeb also sent senior executives. It was probably the greatest single gathering of America's war profiteers.[15] Many of these companies and banks had, like McKittrick, made fortunes from their connections with Germany, connections that carried on producing massive profits long after Hitler took power in 1933 and certainly after the outbreak of war in 1939. Some have been accused of continuing links with the Nazis after December 1941, through subsidiaries in Germany—accusations they deny. The three most powerful sectors were oil, cars, and banks.

Jay Crane, Treasurer, Standard Oil

Walter Teagle, Crane's boss, was a founding board member of General Aniline and Film, IG Farben's American subsidiary. When in 1929 Standard Oil entered into a "division of fields" arrangement with IG Farben—a cartel—IG Farben retained supremacy in the chemicals field, including in the United States, in exchange for giving Standard Oil its oil patents for use anywhere—except Germany, according to a Senate investigative committee.[16] Further agreements followed over the next decade to share technical information and patents. In 1938 Standard sent the full specifications of its processes for synthesizing Buna—artificial rubber—to IG Farben. In exchange, the German chemical combine promised its latest research—once it had permission from the government. Not surprisingly, this was not forthcoming. Thus IG Auschwitz, the firm's massive chemical and Buna factory, run by slave labor and concentration camp inmates, was based partly on American scientific knowledge.

When war broke out in 1939, IG Farben assigned its Buna patents to Standard Oil—to prevent them being seized as enemy property. This was not illegal. But Standard's obstructive policies over development of the Buna industry were. By the time the United States entered the war in December 1941, the country was facing a desperate shortage of artificial rubber. Standard had deliberately delayed the development of the domestic artificial rubber industry by repeatedly telling other American companies that it would share its expertise, even though it had no intention of doing so, to prevent them developing alternatives, according to the US Department of Justice, which brought a lawsuit against the company.[17] In March 1942, six Standard Oil subsidiaries and three company officials were fined five thousand dollars each by a federal judge for violating anti-trust laws. IG Farben was named as a co-conspirator. Thurman Arnold, the assistant attorney general in charge of the Antitrust division, accused Standard of "treason" and entering an "illegal conspiracy" to prevent the development and distribution of artificial rubber. In its defense, Standard claimed that its agreement with IG Farben had resulted in the release of new information about synthetic rubber production, fuel, and explosives.

British Security Coordination, the British intelligence service operating in the United States, was closely monitoring the connections between Standard Oil, GAF and IG Farben, whose CEO, Hermann Schmitz, sat on the board of the BIS. GAF and Chemnyco, another American subsidiary of IG Farben, were the headquarters of Nazi industrial espionage in the United States. British intelligence believed that before the outbreak of war, IG Farben's spy service, "Buro IG," had dispatched deep cover agents to settle in the United States, to make business contacts, and to glean American scientific know-how. Some had married American women and become citizens. Chemnyco was also investigated by the US Department of Justice, which reported that it was a spying operation: "The simplicity, efficiency, and totality of German methods of gathering economic intelligence data are exemplified by Chemnyco, Inc., the American economic intelligence arm of IG Farbenindustrie. Chemnyco is an excellent example of the uses to which a country with a war economy may put an ordinary commercial enterprise."[18]

Donald MacLaren, a BSC operative based in New York, had been working for months on an operation against GAF. MacLaren's plan combined dirty tricks with very public exposure of the firm's links to Nazi Germany. MacLaren, an ebullient Scot and bon viveur, was a forensic accountant by training and an expert in economic warfare. He had untangled the web of connections linking Standard Oil and Sterling Products, an American pharmaceuticals firm, with GAF and IG Farben. GAF, he wrote, was a "supply depot" for the Latin American subsidiaries of IG Farben and sought to "camouflage its German ownership."[19] MacLaren knew that there were two factions in GAF's board of directors. He infiltrated both groups under a false name and gained their confidence. He then persuaded each of his contacts to reveal their faction's plan to outmaneuver the other grouping—information that he promptly passed on to the other side, which produced "an outright quarrel between the two." The result was most satisfactory,

he wrote, with "one faction racing the other to Washington to report the wicked activities of their colleagues to the Department of Justice, thereby exposing their German instructions to the United States government."[20]

MacLaren and his colleagues in British Security Coordination also set up a company called Booktab. The firm published a seventy-page pamphlet entitled *Sequel to the Apocalypse: The Uncensored Story—How Your Dimes and Quarters Pay for Hitler's War* . With a trenchant foreword by Rex Stout, the popular mystery novelist, the pamphlet described, in forensic detail, "the hidden corporate relationships between American organizations and German monopolies." The pamphlet, published in early 1942, demanded the "the full penalty" for German industrialists and bankers, including Hermann Schmitz and Hjalmar Schacht. Two hundred thousand copies were printed. Despite the best efforts of the companies exposed to sabotage the project by buying up as many copies as possible, tens of thousands were sold. The facts about American business links with the Nazis were now out.

Sequel to the Apocalypse caused a nationwide furor. It was certainly a public relations disaster for Standard Oil. The Treasury Department took control of GAF in February 1942 and soon after handed the stock to the newly established Alien Property Custodian. One hundred members of staff known to be sympathetic to the Germans were sacked, from directors to engineers. GAF's research arm was turned over to war production. By 1944 the Custodian had also seized a total of twenty-five hundred patents from Standard Oil and its affiliates. Standard Oil eventually released all its patents for artificial rubber for free.[21]

Meanwhile, in Nazi-occupied Poland, the slave laborers at IG Auschwitz were enduring a living hell of backbreaking work, extreme brutality, and starvation rations. Among them was a teenage boy named Rudy Kennedy. Rudy and his family were deported to Auschwitz in 1943 from the ghetto in Breslau, now Wroclaw, in Poland, when he was fourteen. When the train arrived at the selection ramp, Rudy took his father's advice and lied about his age, claiming to be eighteen:

> *My father and I went to the right, my sister and my mother to the left. The guards kicked and beat us, and we went into a room with showers and basins at one end. My father was naked with hundreds of older men. Everyone was very agitated. They shaved our hair and told us to go into the shower. I was very disturbed by the shoes. All the shoes were piled up and jumbled together in a big heap. I wondered how they were going to sort them out, if we would ever wear them again. We went into the shower. Water came out. By then my mother and my sister were dead. The temperature was about minus ten and we were chased naked and barefoot down a frozen path to a blockhouse. We were given a red blanket and a piece of bread and salami. In the morning we were given clothes, everything at random, nothing fitted. They called out our names and we had numbers tattooed on our arms. The tattoo needle was very thick, like a knitting needle and the blood of the previous prisoner was still running down it.*[22]

Rudy and his father were sent to the IG Farben factory, where he worked at installing electric motors. The extremely harsh conditions were designed to kill off the laborers in a couple of months. Rudy survived because of his specialist knowledge of electrical systems, which meant he had access to food. He became a kind of mascot. One day a supervisor dropped his sandwich on the floor and told Rudy to pick it up. He would not eat it, he told the starving boy, because it was dirty. But Rudy could have it. This counted as an act of kindness. The IG Farben managers were fully aware of what was happening in their

factory, Rudy later recalled. "We saw the civilians from IG Farben all over the place. We worked very near a site where they were building a chemicals factory. We could see people dragging sacks of cement, then they would collapse and die. The IG Farben civilians had to go past that on the way to their canteen. They absolutely knew what was going on. There is no question."[23]

When IG Farben's managers judged their slave laborers to be *gebraucht*, or used up, they were dispatched to Auschwitz I or II, to be dispatched by Zyklon B. Degesch, the German pest control company, which manufactured the poison gas capsules was a subsidiary of IG Farben. Rudy Kennedy survived. His father, Ewald, endured for about two months before being killed by an injection of prussic acid, which fit with IG Farben's planners' calculations about how long a slave laborer could live on his own body fat reserves.[24]

Walter Teagle resigned from the board of Standard Oil in November 1942. Bruised and disappointed by the pillorying he had received in the media, in 1944 he set up the Teagle Foundation with a mission to "advance the well-being and general good of mankind throughout the world." The foundation's reach did not extend to Nazi-occupied Poland but it still exists today.[25]

Donaldson Brown, Vice Chairman, General Motors

War had brought enormous profits to the American car industry. Opel, General Motors' German division, produced the "Blitz" truck on which the Wehrmacht invaded Poland. Ford's German subsidiary produced almost half of all the two- and three-ton trucks in Nazi Germany. There is a strong argument that without General Motors' and Ford's German subsidiaries the Nazis would not have been able to wage war.[26] Hitler was certainly an enthusiastic supporter of the American motor industry's methods of mass production. He even kept a portrait of Henry Ford by his desk.

In July 1938, Henry Ford was awarded the Grand Cross of the German Eagle, the highest honor Nazi Germany could bestow on a foreigner. The following month James Mooney, who ran General Motors' overseas operations, was also awarded a high Nazi honor. Mooney was a regular visitor to Berlin, where he met numerous Nazi officials, including Hjalmar Schacht, to negotiate deals to produce vehicles for the military. In 1939 Mooney even held talks with Hermann Goering on converting the General Motors plant at Russelheim to production of the Junker Wunderbomber.[27]

George Messersmith, the U.S. Consul-General in Berlin, who later served as ambassador to Austria, was watching Mooney's enthusiasm for the Nazis with alarm. Messersmith, despite his German origins, was an ardent anti-Fascist. His reports through the decade detail Mooney's unwavering determination to build up General Motors' links with the Nazis. Mooney, like Sosthenes Behn (the president of ITT whose German partner was the BIS director Kurt von Schröder) believed that the Nazi regime was here to stay in Germany and was "well established," wrote Messersmith in November 1934.[28] Thanks to Schacht's policies and the armaments drive, the German economy was booming. "It is curious that he and Colonel Behn and some other factories in Germany give this opinion. The factories owned by the ITT in Germany are running full time and in double shifts and increasing their capacity for the simple reason that they are working almost entirely on government orders and for military equipment."[29]

Numerous American business leaders traveled to Berlin to ingratiate themselves with the Nazis. Thomas Watson, the president of IBM, arrived in 1937, to be decorated with the Merit Cross of the German Eagle. That was one grade down from Henry Ford's honor. But Watson could comfort himself with the fact that Schacht himself had hosted the ceremony and given a speech in Watson's honor. [30] The following year, after the Nazi annexation of Austria, the SS used one of IBM's prototype computers, known as a Hollerith machine, to keep a record of Jewish properties and their subsequent Aryanization.

The Vienna Nazi party newspaper boasted that thanks to the Hollerith machine, "within six weeks we shall have laid hands on all Jewish fortunes over 5,000 marks; within three years every single Jewish concern will have been Aryanized."[31] The historian Edwin Black argues that IBM's technology, used for cataloging and identifying the Jews of Europe, was crucial for the organization of the Holocaust.[32]

Mooney's medal was certainly a good investment by Hitler. In late 1938, Mooney was still pressing for a trade agreement with Nazi Germany, noted Messersmith, claiming that it would "help the conservative elements in Germany and therefore improve the prospects for a more reasonable regime in Germany," as though a wealthier Third Reich would somehow become more benign. Messersmith dismissed Mooney's claim. His real aim was to "in some way or other help along the important General Motors interests in Germany."[33]

Even in April 1941 Mooney refused to get rid of Axis supporters in the company's overseas subsidiaries, Messersmith wrote to Breckinridge Long at the State Department. "There are some cases like the General Motors, which are not giving us any cooperation in our program to get rid of anti-American agents of American firms abroad. This is due to the fact that there are certain people in the General Motors, such as Jim Mooney, and some of the men whom he brought into the organization over the years, who are really betting on a German victory and who hope to be the big boys in our country if there is a Nazi victory."[34]

Siegfried Stern, Vice President, Chase National Bank

Chase National Bank was the world's largest private bank in terms of assets and deposits. Its New York headquarters was a key hub in the Nazi's global financial network and held accounts for the Reichsbank and Germany's Gold Discount Bank. Chase was so close to the Reichsbank that after the war, Thomas Dodd, a prosecutor at Nuremberg, claimed the bank had once offered Emil Puhl, the vice president of the Reichsbank and BIS board member, a job in New York.[35] The Treasury closely monitored Chase's transactions for its Nazi clients. On October 3, 1940, Merle Cochran sent a note to Henry Morgenthau detailing transfers from Chase's German accounts. In the previous two days alone, $850,000 had been debited from the Reichsbank account, of which $250,000 was sent to the Wallenbergs' Enskilda Bank in Stockholm. A further $1.13 million was transferred from the account of the Gold Discount Bank to Topken and Farley, a firm of lawyers at 17 Battery Place, New York.[36]

Chase National was of special interest to the Nazis because of its overseas branches in London, Paris, Mexico City, and Shanghai. A wartime investigation of the bank's Nazi links, by Paul Gewirtz, a US Treasury official noted, "The Chase Bank, like the other American banks in France, operated on a relatively small scale. The attitudes of the Germans, however, when they came into France, indicates that they looked beyond the activities in France and were more interested in the international character of an organization like Chase with its established branches through the world and its history in international banking which including a friendly intercourse with the Germans."[37] In other words, Nazi Germany valued Chase National, like the BIS, for its transnational reach.

After the German invasion of France in May 1940 the Paris headquarters of Chase National had enthusiastically collaborated with the country's new overlords—with the knowledge of the bank's headquarters in New York, reported Gewirtz.

> *Investigations conducted at the Paris Branch and at the Home Office in New York of Chase Bank disclosed that the bank operated in Paris throughout German occupation and engaged in sundry activities indicate an over-riding desire to continue operating even*

though this required a close collaboration with the German authorities. There is evidence that the Home Office in New York was fully informed of these activities, at least until late in 1942, but took no steps to discourage them, at the same time withholding pertinent information from United States Governmental authorities.[38]

Carlos Niedermann, the manager of Chase's Paris office, was an ardent Nazi sympathizer. He closed Jewish-owned accounts and transferred the assets to Nazi-owned ones. In May 1942, Hans Caesar, a director of the Reichsbank, was put in charge of American banks in France. Niedermann met with Caesar. Caesar held the bank in "very special esteem" because of its New York headquarters. Niedermann recorded, "It is a fact that the Chase Bank enjoys special prestige in the banking circles in question owing to the international activities of our head office."[39]

Thomas Lamont, J. P. Morgan

Thomas Lamont was a senior partner at J. P. Morgan, one of the BIS's founding banks, a veteran of the reparations negotiations and, naturally, a friend of John Foster Dulles. Lamont had represented the US Treasury at the Paris Peace Conference in 1919 and later sat on the Young Plan committee. Like Chase National, J. P. Morgan encouraged its French subsidiary, known as Morgan & Cie, to continue trading with the Nazis, according to declassified US intelligence reports. As the Germans advanced on Paris, the French authorities ordered Morgan & Cie to liquidate their accounts and destroy their stocks of banknotes. Morgan & Cie ignored the order. Instead, like Chase National, the bank opened a new office in Vichy, France, at Châtel-Guyon to service its Nazi clients.

A Treasury investigation reported that "the primary loyalty of the Morgan partners was not to the US or France, but to the firm. Regardless of national considerations, they invariably acted in what they deemed to be the best interests of Morgan et Cie."[40] Morgan & Cie even gained permission to handle payments from German accounts to the European subsidiaries of American firms that were building military equipment for the Third Reich—such as General Motors. This ran so smoothly that Morgan & Cie's American lawyers cabled the firm's French managers to thank them: "The office at Châtel-Guyon has proved to be of great practical utility; without it we could not have carried on any business with the outside world."[41]

SWEDEN, ONE OF the Nazis' most important trading partners, was also represented at McKittrick's dinner, by Lars Rooth, the son of Ivar Rooth, the director of the Rijksbank. Ivar Rooth was one of the world's longest-serving central bankers and a founding member of the new transnational financial elite. He was important enough to be elected unanimously to the BIS board in 1931, even though Sweden was only a shareholder and not a founding member of the BIS. Rooth stayed until 1933 and returned in 1937, praised in the BIS annual report for that year as a banker well known for his "constructive work of collaboration." Working with the Wallenberg brothers at Enskilda Bank, Rooth helped steer Sweden through a neutrality whose profitability was rivaled only by Switzerland's. Swedish firms supplied the Nazis with millions of tons of iron ore to be turned into tanks, guns, and ammunition, with vital ball bearings, foodstuffs, and timber. Rooth, it seemed, was indeed a highly skilled collaborator, although not only in the meaning referred to in the BIS report.

Thomas McKittrick was the third American president of the BIS, after Gates McGarrah and Leon Fraser. The American connection had shaped the BIS since its foundation in 1930. The bank had been ostensibly set up to administer the Young Plan for German reparations, named for the American diplomat

who had brokered the deal. The BIS was the trustee for the loans Germany took out from Wall Street to meet those obligations. The bank's American presidents stood at the center of the network of connections between Wall Street and American industry and Nazi Germany. Standard Oil had formed a cartel with IG Farben, whose CEO, Hermann Schmitz, sat on the board of the BIS. The French subsidiary of J. P. Morgan, a founding member of the BIS, traded profitably with the Nazis after the invasion of France. ITT had gone into partnership with Kurt von Schröder, the powerful Nazi banker who was a director of the BIS. For the new class of transnational financiers, war was merely an interruption in commerce, albeit a highly profitable one. Both McKittrick and his guests were already planning how to maximize their profits in the postwar era. Meanwhile, the money channels had to be kept open, and they ran through Basel. McKittrick embodied the American-Nazi financial network, which is why dozens of the United States' richest and most powerful businessmen and industrialists gathered in New York that freezing December evening to honor Hitler's American banker.

MCKITTRICK REMAINED MAROONED in New York, unable to return to Basel, until Montagu Norman came to the rescue. Meanwhile the BIS president was still a man in demand. Thomas Watson, the president of IBM who had been honored by Hitler, could not attend McKittrick's dinner at the University Club. Instead, Watson, who was also the president of the International Chamber of Commerce, arranged a luncheon in McKittrick's honor. Aware that not all of the American public shared the financiers' enthusiasm for the BIS, McKittrick limited himself to three private formal engagements while in New York. On January 12, 1943, he wrote to Ernst Weber, the president of the Swiss National Bank and chairman of the BIS board, that "it seemed to me best, however, for the BIS not to take part in public or semi-public gatherings."[42]

One day, McKittrick paid a call on a diplomat at the British embassy in Washington, DC. He had reassuring news for the BIS president. The Bank of England and the Treasury were "very interested in the BIS," the British diplomat said. "I've got to take this up with London. I'll be surprised if I can't get you back."[43] Calls were made, cables were sent, and the wheels of transitional finance started turning. Rafaelle Pilotti, the BIS's Italian secretary general, told McKittrick to travel to Lisbon and report to the Italian Legation, which would help him get to Rome, and from there he could travel on to Basel. McKittrick eventually received permission to leave the United States and arrived safely in Lisbon. After a stop in Madrid, he flew to Rome.

The United States was at war with Italy, and McKittrick was a citizen of an enemy nation, but none of that mattered. The BIS president still received a regal reception, he recalled. "I was met at the airport as if I was the king of something. Nobody looked at my passport; they just waved their hands at it." McKittrick was then taken to a comfortable hotel where Pilotti met him. Understandably, the Italian authorities did not want an American banker wandering freely around Rome. Pilotti arrived, to act as McKittrick's minder. The two men sent out for a sumptuous dinner. "That was the best meal that I ever had in the war, and Italy was really short of food, but good gracious they gave me a wonderful meal," recalled McKittrick. Soon after, at 11 p.m., McKittrick was put on a train to Switzerland.[44]

McKittrick finally arrived back in Basel in April 1943. His trip to the United States had produced mixed results. Despite his lobbying and John Foster Dulles's legal advice, the BIS's request for exemption was denied. The bank's funds in the United States remained frozen. But if that battle was lost, a far larger one loomed: for the bank's very survival. This time Henry Morgenthau, rather than McKittrick, would find himself outgunned.

> *"The bearer of this letter, Mr. Thomas McKittrick, President of the Bank of International Settlements, is a close friend of a prominent member of the State Department stationed in Switzerland, Mr. Allen Dulles."*
>
> — OSS *laisser-passer* for Thomas McKittrick, June 15, 1945, requesting the provision of US Army billet and mess facilities[1]

There were many in Washington, DC, especially in the Treasury department, who asked why the State Department had renewed McKittrick's passport and allowed him to return to Basel, when it was clear that the BIS was aiding the Nazi war effort. The answer lay in Bern, at Herrengasse, 23. Here McKittrick's old friend and protector, Allen Dulles, ran the Swiss branch of the Office of Strategic Services, America's foreign intelligence service—a complex network of bankers and businessmen, scholars and spies, and refugees and émigrés. Some of Dulles's assets and agents traded information out of principle, others for money. McKittrick, also known as OSS codename 644, traded information out of loyalty—not to the Allied cause or the national interest of the United States, but to transnational finance, a creed shared by America's spymaster.

Back channels between the Allies and the Axis powers existed throughout the war in neutral capitals such as Stockholm, Berne, and Lisbon. The BIS was one of them. Its multinational staff and neutral, privileged status made the bank an ideal place for gathering and disseminating intelligence. Switzerland was its natural home. As the cynical wartime saying noted, "For six days a week Switzerland works for Nazi Germany, and on the seventh it prays for an Allied victory." After his return to Basel in 1943, McKittrick regularly met with Allen Dulles and American ambassador Leland Harrison. The three men, McKittrick recalled, talked more freely "in those meetings than at any other time." Dulles and Harrison wanted to know everything McKittrick knew, especially about Nazi money channels—which was a lot, McKittrick later recalled,

> *And I did know, for instance, the way the Germans were obtaining the money with which they maintained their organisation for sabotage, subversion, as well as political and military intelligence, especially in South America. The Allies were very anxious to stop this, but no way was found to do so without risking a loss of good will among the neutral nations which would be too serious to provoke.*[2]

The Portuguese connection was key, McKittrick explained to Dulles and Harrison. The Germans needed a steady supply of Portuguese escudos to pay for vital war materials such as tungsten. The Portuguese escudo was then a hard currency, accepted by the Allies, the Axis powers, and of course, South American countries. Some German companies were still connected to their American partners or parent firms through subsidiaries in South America. The key players were the Bank of Portugal, the Reichsbank, the Swiss National Bank, and the BIS. The Bank of Portugal bought gold bullion from the Reichsbank, which was delivered to the Swiss National Bank and credited to the Bank of Portugal's account. The Bank of Portugal then credited the requisite amount of escudos to German accounts in Lisbon, allowing German purchases to take place there.

Germany was also shipping gold to the BIS, McKittrick explained,

> *You see we had a lot of German investments, which were made in '31 in accordance with the statutes of the bank. We had to help Germany with loans to pay for reparations payments in the first years . . . they had to pay us about a million Swiss francs a month and that is what we lived on. And in order to give us that money they would ship gold to us. Now, we had no vaults. We had no place to handle gold. We had none of the necessary devices to assay gold or weigh gold. They [the SNB] have a scale as big as that chimney breast there, and you can weigh the weight of your signature on a piece of paper. So we had the Bank of Switzerland do all our gold handling and gold storing for us in Switzerland.*[3]

The American government knew this. A source referred to as "A" passed intelligence about BIS gold movements to American officials in Bern. It was sent to the State Department in a cable dated June 23, 1943:

> *German gold shipments (gold bars) arriving here, which were referred to recently, seem to be for the account of the Bank for International Settlements. The value involved is small, approximately Swiss francs 750,000 at a time. The gold, upon the arrival at the National Bank of Switzerland, Bern, is passed to the credit of the Basel bank.*[4]

The BIS also held gold for the Reichsbank so sometimes, when the interest was due on the bank's investments, the BIS simply helped itself to the Nazi gold it held to make up the payments, McKittrick explained. At other times, the Germans borrowed BIS gold for their dealings with Swiss banks. This cozy arrangement caused no concern at the BIS, said McKittrick, as "we knew that they'd replace it." McKittrick's close relationship with Emil Puhl, the vice president of the Reichsbank, was especially valued by Dulles and the OSS. Puhl, whom McKittrick described as a "friend," passed on important information about German morale, the country's economy and political intrigue. OSS telegram 3589-90, sent on May 25, 1944—at a time when thousands of Hungarian Jews were still being deported every day to Auschwitz, where most were immediately murdered—records Puhl's fears—not that the war was lost, but that the Reichsbank might lose its privileged position during the reconstruction.

> *Not long ago our 644 [McKittrick] had two lengthy conversations with Puhl of the Reichsbank. The latter was extremely depressed, not so much by the idea of Nazi defeat, but by the situation, which Germany will have to contend with later. The Reichsbank has been engaged in work on plans for the reconstruction, and evidently they are unable to see where an effective beginning can be made.*[5]

Roger Auboin, the BIS manager, was known as OSS codename 651. Auboin naturally had excellent connections in France. OSS telegram 3401, sent on May 11, 1944, warns that the Nazis planned to plunder what remained of French national assets:

> *I have been informed by 651 that he is the recipient of secret information from Paris pointing out the danger of an attempt to seize both the French Treasury and Bank of France's gold and foreign exchange.*[6]

McKittrick also had excellent connections in neutral Sweden. The Stockholm OSS station closely

observed Jacob Wallenberg and his brother Marcus, of Enskilda Bank. Jacob, the author of the Swedish-German trading agreement, was the most powerful banker and businessman in Sweden. He had strong links with both the Nazi leadership and the German resistance. His brother Marcus was McKittrick's mentor at the BIS since the two men worked together on the German Credits Committee during the 1930s, when Wallenberg had taught McKittrick about the intricacies of international finance.

When Marcus fell ill in June 1943, McKittrick wrote an appreciation of the Swedish banker, which was hand delivered by Ivar Rooth, the governor of the Rijksbank. "During the three years I have been in Basel," wrote McKittrick, "your method of approaching international problems, of which I gained some understanding during our work together in Berlin, has helped me more than I can tell you in dealing with the intricate and delicate questions which have presented themselves to the Bank for International Settlements by reason of changes wrought by the war." Marcus Wallenberg was his most important teacher, McKittrick concluded. "The thought of following in your footsteps will provide spur to my will and a goal for my ambition."[7]

The most important lesson the Wallenbergs could teach McKittrick was how to play both sides at once: ensuring that Sweden remained one of Nazi Germany's key trading partners while feeding intelligence to the Allies—and thus guaranteeing that regardless of whoever won the war, the Wallenberg banking and business empire would survive and thrive. Jacob Wallenberg managed the bank's channel to Berlin while Marcus looked after connections with the Allies. As the managing director of the Enskilda Bank, Jacob Wallenberg was the "principal financial figure in Scandinavia" and was "vigorous, shrewd, and cautious," Abram Hewitt, an OSS agent based in Stockholm, reported.[8] Outside the Swedish foreign office, Jacob Wallenberg was the country's "principal representative" dealing with Nazi Germany. "Wallenberg frequently goes to Germany and most Germans of importance visiting Stockholm are in touch with him."[9]

Sometime in 1943, Wallenberg had asked Hewitt if he would like to meet representatives of cells forming in Germany who planned to overthrow Hitler. Nothing came of this as the cells were subsequently "liquidated." In 1944 Wallenberg claimed to know the names of German generals who were now opposed to Hitler—because of German defeats—and were ready to overthrow him. However, he would share the names only when "in his opinion conditions would justify it." Wallenberg "probably has better sources of information about Germany and the continent in general than any man in Sweden," Hewitt continued. However Wallenberg was a "very difficult" man to approach, except by someone whom he had known for a long time. Jacob Wallenberg was still a bachelor at the age of fifty-four, and one possible approach of getting to know him was the time-honored one of the honey trap, preferably on a yacht. "It is important for anyone dealing with Jacob Wallenberg to know that he is very interested in sailing and in attractive women." Marcus Wallenberg, his young brother, was quickly dismissed, as a "man of less integrity and less weight."

Meanwhile, in Washington, DC, the Treasury was also closely monitoring the Wallenberg brothers and Enskilda Bank. A Treasury report in December 1944 made numerous accusations of economic collaboration with the Nazis: "Jacob Wallenberg recently indicated that he was willing to sell to the Germans a Swedish plant in Hamburg for gold, provided the price was high enough to compensate for possible future complications from the Allies."[10] Enskilda Bank acted for the German interest in the American branch of the Bosch company and had also worked with the Swiss Bank Corporation to conceal German interests in Schering, a chemical company in New Jersey—which had since been vested by the Alien Property Custodian, the report noted.[11]

J. Holger Graffman, Wallenberg's point man for foreign currency deals, was regarded as a high-value asset by the OSS. Graffman, an engineer by training, had worked as Latin American representative of Ivar

Kreuger, the Swedish fraudster bankrolled by Lee, Higginson, the former employers of Thomas McKittrick. After Wallenberg had taken control of the remains of Kreuger's empire, Graffman returned to Sweden and joined Enskilda Bank, working on currency transfers, foreign credit, and blocked accounts. "In my opinion this man is the most useful single contact there is for us in Sweden. He is very pro-American and is married to a Dutch woman whose feelings toward the Germans are what you would expect," noted Hewitt.

But Graffman was also friends with Felix Kersten, an Estonian-born masseur who now lived in Stockholm. Kersten's most important client was Heinrich Himmler and he frequently returned to Berlin to treat him. Graffman introduced Hewitt and Kersten over coffee and cakes at his house. Kersten began treating Hewitt for his back problems. But Kersten was much more than a masseur: soon afterward he brokered a meeting between Hewitt and Walter Schellenberg, the Nazi intelligence chief, in Stockholm. Schellenberg and Hewitt met in Kersten's office in November 1943. Schellenberg hoped to arrange a separate peace with the Western Allies to prevent a Soviet takeover of Eastern Europe. The plans came to nothing.[12]

The Wallenberg business empire was the most important transnational finance channel between Sweden and Nazi Germany. Not just money but vast amounts of intelligence flowed back and forth between Stockholm and Berlin. Much of the State Department and the OSS—especially Allen Dulles—shared Jacob Wallenberg's desire to keep links with German industry so that business could resume as swiftly as possible after the end of the war. An OSS psychological warfare operation known as the "Harvard Plan" specifically utilized Thomas McKittrick for this purpose. The Stockholm OSS office published a wartime newsletter for German businessmen filled with snippets of intelligence and news. The purpose of "Information for German Business," was to suggest that cooperation now would pay handsome dividends after the Allied victory. OSS officials believed that the newsletter was seriously affecting the morale of German businessmen, many of whom were now planning for their future in a post-Nazi Germany.

On February 1, 1945, David Williamson, a senior official in the OSS Morale Operations department, wrote to codename 110—Allen Dulles. Williamson suggested to Dulles that he set up a similar psychological warfare operation in Switzerland, or find another way to use the Harvard Plan material to erode German morale. Williamson enclosed some draft material for Dulles's perusal. Notably, all the information in the OSS Stockholm newsletter had been passed by the State Department before it was to be distributed. The newsletter included this paragraph:

> *The direct negotiations, which have been taken up by the business interests on both sides thanks to the mediation of Mr. McKittrick, the American who lives in Basel, have already led to a number of detailed agreements. Thus, we learn that representatives of the German potash industry have contacted and entered into binding agreements with the new and expanded potash industries overseas . . . it is expected that the postwar demand permanently will be materially higher than pre-war consumption. The new agreement will guarantee the German export interests during this second period an export income at least equal to their pre-war revenues regardless of the expected break in the German cartel control.*[13]

Once again, the German chemical industries were key. In 1925 Lee, Higginson, McKittrick's employers, had been part of a syndicate, including Enskilda Bank, that had issued an £8 million bond on behalf of the German Potash Syndicate. Nineteen years later, McKittrick was still ensuring that supplies of the mineral, vital for agriculture, would continue after the war's end. A second paragraph, also

datelined Basel, outlines how, even as Allied airmen were bombing Germany, McKittrick had already concluded an agreement to "preserve the industrial substance of the Reich." Anyone who questioned the wisdom of such backdoor accords was merely a "leftist radical":

> *Mr. Thomas H. McKittrick, the American president of the BIS, has announced his decision to continue his efforts for a close cooperation between the Allied and German business world, irrespective of the opposition of certain leftist radical groups; in these efforts he counts on the full assistance of the American State Department. "After the war such agreements will be invaluable," said McKittrick. We learn that certain German interests have received assurances that their negative attitude toward the National-Socialist regime will be fully be considered by the Allied political and economic leadership after the war. Negotiations are under way to bring hostilities to a speedy conclusion and to preserve the industrial substance of the Reich.*[14]

Thus, while American and Allied troops were fighting their way across Nazi-occupied Europe, Thomas McKittrick, an American citizen, was using his position at the BIS—with the knowledge of the State Department—to try and bring Allied and Nazi businessmen together, to plan for a post-war Germany that preserved as much as possible of the country's industry. McKittrick was even brokering agreements to guarantee German companies' postwar profits and to help German industrialists avoid the financial consequences of the break-up of prewar cartels.

THE OSS MEMO on the Harvard Project also noted how profitable Cicero's "sinews of war" had been for the American oil industry, most of all for Standard Oil. Oil industry dividends in 1944 reached a new high of almost $300 billion, the memo noted, quoting the *Wall Street Journal*—nearly a fifth more than in 1943. Standard Oil alone would pay out $68.3 million.

With such enormous sums moving around the increasingly globalized economy, it was becoming more clear that the world would need a new international financial system to finance postwar reconstruction and stabilize trade. In July 1944 more than seven hundred delegates from the forty-four Allied nations gathered at the Mount Washington Hotel in Bretton Woods, New Hampshire, for the United Nations Monetary and Financial Conference. Henry Morgenthau and Harry Dexter White led the American delegation. The conference agreed on the creation of the International Monetary Fund (IMF) and an International Bank for Reconstruction and Development (BRD), which became part of the World Bank. The IMF would monitor exchange rates and lend reserve currencies to indebted countries. The new bank would provide loans to underdeveloped countries. Bretton Woods also gave its name to a new international currency exchange system, where currencies were linked to the US dollar. In exchange the United States agreed to fix the price of gold at $35 an ounce. There would be no more currency warfare or manipulation.

But if there was consensus on the basics, there was none on the future of the BIS. With the IMF at the center of the new international financial system why was the BIS still needed? Henry Morgenthau and Harry White wanted the bank to be abolished. On July 10, 1944, they seemed about to get their wish. Wilhelm Keilhau, of the Norwegian delegation, introduced a motion to liquidate the BIS:

> *Be it resolved that the United Nations Monetary and Financial Conference recommends the liquidation of the Bank for International Settlements at Basel. It is suggested that the*

liquidation shall begin at the earliest possible date and that the governments of the United Nations now at war with Germany appoint a Commission of Investigation in order to examine the management and the transactions of the Bank during the present war.

No delegation spoke publicly in defense of the BIS. But behind the scenes its defenders—sections of the State Department, Wall Street, the Bank of England, the British Treasury, and Foreign Office—went into action. Johan Beyen, the hapless Dutch former president of the bank who had handed over the Czechoslovak gold, blamed the US Treasury Department, in particular Harry White for the resolution. White, Beyen claimed, had got the Norwegians to do his "dirty work." White certainly supported the motion, which he believed would force McKittrick to resign, an event he described as "a salutary thing for the world."[15] White's opposition to the BIS—and clear understanding of its wartime role for the Nazis—had long caused alarm at the Bank of England. In December 1943, E. W. Playfair, a senior official at the bank, had written to Otto Niemeyer, the former chairman of the BIS board, drawing his attention to an article in the *New York Times* about White and the BIS. White had "disparaged" the bank and said it had "no significance" in relation to plans for the postwar reconstruction of Europe. Germany, said White, was being nice to the BIS because it hoped to use it to "get back into financial power."[16] White was even more scathing about McKittrick, describing him as "an American president doing business with the Germans while our American boys are fighting Germans." All of which was true and so even more infuriating for the financial mandarins, who preferred to keep their arrangements with the other side out of the public eye.

The Foreign Office advised the British delegation that any resolution dealing with the BIS or its liquidation would be "improper," that most British of sins. Britain, from the start, had been "opposed to doing anything with respect to the BIS," noted Orvis Schmidt, a US Treasury Official.[17] So was Wall Street. Leon Fraser, said Morgenthau, was "one of the spearheads of opposition to what we are doing here and has surrounded himself with a group who are fighting what we are doing here. . . . Now I don't say that Mr. Fraser isn't a very fine American citizen, but he has certain loyalties which run there, just the way Mr. McKittrick has, Mr. Beyen has. . . ." The BIS was a kind of club for central bankers, said Morgenthau and people like Schacht and Funk still hoped that the "same kind of thing would continue after the war."[18] Morgenthau was an implacable opponent not just of the BIS but of any kind of reconstruction that would allow Germany to dominate Europe. His plan for the country called for German heavy industry to be dismantled or destroyed, for Germany's industrial areas to be internationalized or ceded to neighboring countries, for complete demilitarization, and for the country to be reduced to a pastoral or agricultural economy.

Harry White saw the BIS clearest. The bank's emphasis on its supposed neutrality was an alibi for its future role in reconstructing Europe, he argued:

They hope to be a moderating influence in the treatment of Germany during the peace conference. That is why Germany has treated it with the greatest of care. She has permitted her to pay dividends; she has let the people in BIS come and go across enemy territory; she has been extremely careful and well-disposed to the BIS, because she nursed that baby along in the hope that that would be a useful agency that would protect her interests beyond those that any other institution around the peace table would.[19]

On July 18, Ansel Luxford, a member of the US delegation, proposed a new resolution, that no country

could join the IMF unless it had "taken the necessary steps to foster the liquidation of the BIS." John Maynard Keynes, the influential economist who was part of the British delegation, was furious. Keynes, who was also close to John Foster Dulles, suffered from angina and became so agitated by the affair that there were rumors he had suffered a heart attack. He demanded that the resolution be withdrawn or he would quit the conference. There could be no linkage between dissolving the BIS and joining the IMF, Keynes wrote to Morgenthau, or Britain would not participate in either the IMF or the new bank for an "indefinite period."[20] Morgenthau backed down.

Eventually, a new Norwegian-Dutch resolution calling for the liquidation of the bank at the "earliest possible moment" was finally agreed. It was a perfect compromise: critics were satisfied that the principle was now established that the BIS must be closed down, while the bank's supporters noted that the resolution set out no date or conditions for this eventuality. Beyen, the former BIS president, distanced himself from the bank, rapidly remodeling himself as a pillar of the postwar democratic order. The BIS was incompatible with the IMF, and its statutes and banking operations would be obsolete after an Allied victory, he now argued. Little wonder that Beyen was described by Orvis Schmidt as a "very shifty fellow" who had "demonstrated his ability to forget what he said five minutes earlier."[21]

The Bretton Woods conference was watched with intense interest in Berlin. Puhl and the Nazi bankers understood that whatever was agreed upon by the fractious delegates, the BIS, or something like it, would survive. There were too many vested interests, on both sides of the conflict, to allow the world's most important channel of transnational finance to be closed down—especially when it had consistently proved its worth under the most arduous of conditions. An article in the Berlin newspaper *Das Reich*, published in September 1944, argued that the global economy was now so complex that an international clearinghouse would be needed once the war was over. The new IMF and IBRD would not be able to perform these functions. Even if the Allies were unwilling to hear "the un-speakable name of the BIS" they would need something like it.[22] *Das Reich* was correct.

IN BASEL, MCKITTRICK was enraged by the attacks on the bank. He wrote to the Bank of England and demanded a full investigation into the BIS's wartime record, which he apparently believed would exonerate him. The prospect of that set off alarms from Whitehall, the British government quarter, to Threadneedle Street, where Lord Catto, the new governor of the Bank of England had taken over from Montagu Norman. McKittrick, noted a Foreign Office memo, had gone native in neutral Switzerland and was "thoroughly out of touch with the way people are thinking nowadays."[23]

The end of the war did not seem to bring McKittrick any closer to reality. In March 1945 Orvis Schmidt, the US Treasury official who had attended the Bretton Woods conference, met with McKittrick in Switzerland. Schmidt, like his boss Henry Morgenthau, was not a fan of either McKittrick or the BIS, and McKittrick knew it. "It was clear that Mr. McKittrick was fully aware of the manner in which he and the BIS are regarded by the Treasury Department," Schmidt wrote.[24] McKittrick tried his best to persuade Schmidt otherwise—if only the Treasury Department understood "the real role that he and the BIS had played" all that would change, the BIS president ardently believed. This seemed unlikely, considering what followed.

Schmidt continued, "The BIS, McKittrick said, had been 'strictly neutral' during the war. The bank was a 'sort of club' for the world's central bankers, a 'little group of like-minded-men who understood and trusted one another.'" This trust was unimpaired by issues such as national, political, or governmental interests. Rather it was a kind of celestial understanding. It would continue "regardless of the condition of the world or of the constantly changing political relations between their respective countries."

Unimpressed by McKittrick's eulogy, Schmidt asked McKittrick why the Germans had allowed him to run the BIS in this manner—what was in it for them? In response, McKittrick claimed that, "In order to understand the conduct of the Germans toward the BIS, one must first understand the strength of the confidence and trust that the central bankers had in each other and the strength of their determination to play the game squarely." McKittrick then said that the German members of this elite could positively influence the German government's conduct. These financiers, said McKittrick, were not Nazis but were needed by the Nazis because of their technical skills. "The existence of this little group is the keystone in the explanation of Germany's conduct with respect to the BIS," he explained.[25]

Schmidt asked McKittrick if he could name any members of this group. Only one name was forthcoming: Emil Puhl—the vice president of the Reichsbank, BIS director and guardian of looted gold, for which he would soon be put on trial at Nuremberg. McKittrick admitted that the BIS had accepted payment in gold from the Germans during the war. It had all been kept separately so that it could be checked easily to see if any was looted. McKittrick justified this on the grounds that "he thought it would be better to take the gold and hold it in this fashion rather than refuse it and let the Germans use it for other purposes." [26] The conversation then took a surreal turn. Puhl, McKittrick continued, knew where the looted Belgian gold was: in the vaults of the Reichsbank, where Puhl was holding it "for return to the Belgians after the war," rather as a fence might justify his possession of stolen goods to police investigating a robbery. McKittrick also admitted that the BIS had supplied the Third Reich with foreign exchange. But by doing so, he suggested, the BIS had actually weakened the Nazi economy, as Germany had paid more into the BIS in foreign exchange than it had received. Schmidt was incredulous. "I was surprised that a voluntary recital intended as a defense of the BIS could be such an indictment of that institution," he wrote to Henry Morgenthau.

An American intelligence report on the bank's wartime activities, prepared in December 1945, was even more damning. Much of the report was based on interrogation reports of Emil Puhl, who was singing like the proverbial canary in an effort to save himself from a lengthy prison sentence. Puhl revealed how the Reichsbank had used the BIS to pull out its money from neutral countries before it was blocked and then traded the rescued funds with the BIS. He said that German officials had wanted McKittrick to be reelected as his opinions were "safely known" and that the BIS was also of great value to the Reichsbank as an "open window to financial information about the outside world." Much of this information, it seems, was provided personally by McKittrick in his conversations with Emil Puhl. Perhaps the most shocking revelation is that McKittrick, after his return from the United States in May 1943, reported to Puhl directly on "the general picture of the current opinions and financial problems in the United States." McKittrick, the report notes, also provided Puhl with advance information about the Allied Tripartite Mission to Switzerland in February 1945, when the Allies pushed Swiss officials to freeze Nazi assets and stop trading with Germany.[27]

McKittrick was not the only BIS manager providing Puhl with intelligence and acting as a go-between for both sides. When Allen Dulles arrived in Bern, one of the first people he met was Per Jacobssen, the BIS's economic adviser. The spymaster and the economist were introduced at a charity party hosted by the wives of the American and British ambassadors. Bern, like Lisbon, Madrid, and Stockholm, was crowded with legions of spies, informers, and secret agents, trading in information, gossip, and intrigue. Dulles and Jacobssen had much to discuss.

As a Swedish national and high-ranking BIS official, Jacobssen was of extreme interest to both the Allied and Axis intelligence services. Jacobssen could freely travel to and from Allied and Axis territory. Jacobssen, like his compatriots the Wallenberg brothers, played both sides. When Jacobssen returned from the United States in the spring of 1942, he discussed American attitudes toward Germany with Emil

Puhl, the vice president of the Reichsbank.[28]

Jacobssen also relayed valuable information about the British General Staff to Puhl. In the summer of 1942, Jacobssen asked Paul Hechler, the head of the BIS's banking department, who was also a Nazi party member, to pass some news on to Puhl when Puhl next visited Basel: Jacobssen's British brother-in-law, General Sir Archibald Nye, had been appointed vice chief of the General Staff. This was valuable intelligence. Both sides carefully watched staff movements among their enemies' military leadership. The arrival or departure of senior officers could herald new strategies or fresh thinking and herald the rise or decline of a particular commander. Aware that he was breaking a confidence, Jacobssen recorded in his diary that Nye's promotion should be kept from the press: "Puhl said he was glad to be told. We might make a gentleman's agreement between Hechler, himself and me not to mention it further. . . . I pointed out that when it was said in London that what I wrote was too friendly to Germany, these journalists obviously did not know who my relatives were."[29] Thankfully for Jacobssen, "these journalists" also did not know that he was passing valuable military information to the Reichsbank.

Jacobssen, accompanied by Hechler, met Puhl in Zürich on May 1, 1943. Puhl and the Reichsbank wanted information about the different plans circulating in Washington for postwar currencies and trade. Forward-thinking Nazi officials were already planning ahead for the postwar era. They needed to know what the Allies were thinking. As ever, Jacobssen was ready to help. The meeting must be discreet, Hechler emphasized to Jacobssen. "Puhl would of course be suspect if people in Germany heard that he had been in Switzerland to discuss these plans, but Puhl hoped, of course, that still one day it would be possible to come to an arrangement with the enemy," Jacobssen recorded in his diary.[30] "Arrangements with the enemy" were why the BIS existed. Puhl's wish was granted. The following month Jacobssen made a speech in Berlin to German commercial bankers, entitled "The Anglo-American Currency Plans," where he shared his thoughts on Allied postwar economic planning, based on what he had learned in the United States.

Thanks to the BIS's economic adviser, Allied postwar economic plans were now public knowledge in Nazi Germany. Yet it seems unlikely that Jacobssen gave this speech without the permission of the United States authorities. As the OSS documents on the Harvard Plan reveal, the US government ensured that the channels to Nazi industrialists and businessmen remained open, even as American and British soldiers walked into a hail of machinegun bullets on the beaches of Normany. Jacobssen's speech, delivered in German, was translated by the American Legation in Bern and wired to Washington.[31] Jacobssen also passed information on to his brother-in-law Archibald Nye that was useful to the Allies. In 1940, after visiting Berlin, Jacobssen wrote to "Arch," advising Britain and France not to aid Finland in its war with the Soviet Union, as they might soon be on the same side as Russia, fighting the Germans. The letter, said Nye, had been of great value, and he had passed it on to the Foreign Office and intelligence services.[32] Jacobssen, like McKittrick, considered himself above national loyalties, but his heart at least seemed to be with the Allies. He listened to the nine o'clock news from London every night. When the national anthem was played at the end, he rose and stood at attention.

Meanwhile, German anti-Nazi émigrés believed that Georg von Schnitzler, a board member of IG Farben, used the BIS to communicate with the Allies. Von Schnitzler was certainly well placed to send messages to London and Washington. As the sales and commercial chief of the chemical conglomerate, he was one of the Third Reich's most powerful businessmen. Von Schnitzler's boss, Hermann Schmitz, sat on the BIS board. Before von Schnitzler joined IG Farben, he had worked for J. H. Stein, the Cologne bank where Kurt von Schröder was a director, and which ran Special Account "S," Himmler's private slush fund. By 1943, like most German industrialists, von Schnitzler understood that the war was lost. Germany would soon fall under international control, hopefully under the Western Allies. The priority

was to preserve IG Farben's factories, sites, and offices so that the chemical conglomerate could quickly resume its dominance after the hostilities were ended.

Von Schnitzler used the BIS to send a message to the Allies that the bombing of German industry had to stop, according to Heinz Pol, who was a former associate editor of the *Vossische Zeitung*, Germany's paper of record until it was dissolved in 1934. Pol had excellent sources among German émigrés and in neutral countries. He wrote,

> *According to information emanating from Lisbon, Schnitzler is said to have drawn up a memorandum, which he has sent to the board of directors of the Bank for International Settlements at Basel, Switzerland. It is not known whether the memorandum arrived in Basel in time for the general meeting, which took place at the beginning of June (the American Mr. McKittrick presiding as usual), but several points raised in the memorandum are known. Schnitzler, the Lisbon sources say, stresses the fact that the term "unconditional surrender" implies that the Germans will still have something to surrender. But if the war of destruction, especially the bombing of the industrial centers in Germany, goes on, then there will be nothing left in the end but ruins and ashes.*[33]

Schnitzler's terms were clear, wrote Pol: "Collaboration on condition that German industry survives." If the bombs stopped falling, the German industrialists would cooperate with the forthcoming occupation. As none of the IG Farben main sites had been much damaged by bombing so far, von Schnitzler's offer "might not sound too unreasonable to other industrialists on the side of the United Nations."[34]

THE BIS WAS used by Japan as a channel to try and negotiate a peace treaty. Japan was a founding member of the bank and kept its links with Basel during the war. In July 1945 two Japanese bankers, Kojiro Kitamura, a board member of the BIS, and Kan Yoshimura, the head of the BIS's Exchange Section, asked Per Jacobssen if he would act as an intermediary to arrange a peace accord. The Allies demanded unconditional surrender, but the crucial point for Tokyo, the bankers said, was that Japan would retain the royal family, and ideally, the country's constitution.[35] Jacobssen, naturally, passed the information to his close friend, Allen Dulles, who took the Japanese proposal to Henry Stimson, the secretary for war. They discussed it in Potsdam on July 20, 1945, but events soon overtook the slow pace of the backdoor diplomacy. On August 6 Hiroshima was destroyed by an atomic bomb, followed by a second one in Nagasaki on August 9. Six days later Japan surrendered.

Jacobssen at least had the excuse that he was a citizen of neutral Sweden to justify his contacts with the Nazi bankers. McKittrick, whose homeland was at war with the Third Reich, did not. Cocooned in Basel, the BIS president seemed to have lost touch with reality, let alone morality. McKittrick had spent the war years in a parallel universe, one in which neutrality meant that the Reichsbank—the financial motor of war, plunder, and genocide—was judged equal to those banks whose assets it had stolen. A place where Puhl, the Reichsbank's vice president and receiver of stolen goods, was actually helping the victims by keeping their goods in a safe place, and where Puhl—and doubtless Hjalmar Schacht as well—were not the builders and managers of the Nazi economy. Instead they were merely technocratic bankers, who only wanted to "play the game squarely."

It is hard to judge which is worse: that McKittrick really believed these arguments, or they were a cynical lawyer's ploy to ward off difficult consequences. McKittrick was certainly nervous about

possible consequences of his entanglements with Nazi bankers, especially with Paul Hechler, the head of the banking department, who continued to sign his correspondence "Heil Hitler" throughout the war. Fate came to McKittrick's rescue when Hechler died in 1945. His death "raises a serious administration problem while solving a political one," wrote McKittrick to Roger Auboin.[36] But with Allen Dulles covering his back, McKittrick had nothing to worry about. McKittrick traveled to Germany at least twice in 1945 and in September stayed at Allen Dulles's house in Dahlem, in Berlin. Although McKittrick was still president of the BIS, his laisser-passer was organized by the OSS and numerous senior American officials received him.

Not everybody shared Dulles's enthusiasm for the BIS's president. There was a nasty surprise waiting for McKittrick on his return to Basel. The October 11 edition of the *New York Herald Tribune* carried a scathing attack on the BIS, and the article was reprinted in the *Tribune de Lausanne*, a Swiss newspaper. The article reported that the American occupation authorities in Germany were investigating whether the BIS had supported Germany's gold operations and helped finance Nazi rule in other countries. McKittrick's activities during the war were criticized. The bank may be called to give evidence on its gold transactions with Germany during WWII, it added. Hypersensitive as ever to press criticism, and doubtless mindful of his need to find a new job in the United States, McKittrick asked Allen Dulles to take action. The source of the leaks, he suspected, was an American official named Fox, whom McKittrick had met in Frankfurt. Fox was a colleague of Harry White. "White and his associates have taken consistently an extremely unfriendly attitude toward the BIS and the attacks on the bank at the Bretton Woods conference originated with White," complained McKittrick.[37]

Despite the bad publicity and attacks on McKittrick, the bankers at Basel got on with what they knew best: keeping the money moving. Quietly, carefully, barely noticed by the outside world, the BIS returned to business as usual. In December 1946 the bank held its first postwar directors' meeting. Maurice Frere, the governor of the National Bank of Belgium and BIS board member, traveled to Washington, DC, to lobby US policymakers to free the BIS's blocked assets and to try to defuse the media attacks. He found a sympathetic hearing. The turning point came in May 1948 when the BIS agreed to return 3.74 metric tons of looted gold to Belgium and the Netherlands. In exchange, the Allied Tripartite Commission, which dealt with Nazi plunder, agreed to drop all future claims against the bank. The US Treasury freed all BIS assets. Frere was elected president of the BIS, the bank's first since Thomas McKittrick's term had come to an end in June 1946. The Bretton Woods resolution calling for the BIS to be liquidated quietly faded away.

MEANWHILE, THOMAS MCKITTRICK had a lucrative new job. Soon after he stepped down as BIS president in 1946, he was appointed a vice president of Chase National in New York, in charge of foreign loans. McKittrick was even lauded by those whose stolen goods he had purveyed. He was invited to Brussels and decorated with the royal Order of the Crown of Belgium. The honor, noted a press release, was "in recognition of his friendly attitude to Belgium and his services as President of the Bank for International Settlements during World War II."

PART TWO: **BUNDESREICH**

> *Our whole concept of the unification of Europe was that it would first contribute to economic unification. Then we hoped to secure an economic-military unity and finally a political unity.*[1]
>
> — Averell Harriman, US Special Envoy for the Marshall Plan for the postwar reconstruction of Europe

Thomas McKittrick opened his hotel door to find fifteen slips of paper on the floor. It was the spring of 1947, and McKittrick, vice president at Chase National Bank, was passing through London. The messages from the switchboard indicated that someone in Washington, DC, was urgently trying to get in touch. McKittrick asked the operator to phone the number, and the call went through soon afterward. A voice said, "Is that you, Tom? This is Averell Harriman. You're coming to work for me for six months. I talked to Winthrop this morning, and he said you could."[2]

"Winthrop" was Winthrop Aldrich, the chairman of the board of Chase National Bank. Aldrich, who had run the bank since 1934, was one of the best-connected financiers in the United States. His father, Nelson Aldrich, had given his name to the plan, which had eventually resulted in the creation of the Federal Reserve system. Winthrop Aldrich was now an outspoken advocate of economic aid to Western Europe. Aldrich and McKittrick were old friends. In December 1945, at the height of the political attacks against McKittrick and the BIS over their acceptance of Nazi gold, McKittrick had written to Aldrich, complaining about "the people in Washington who seem to dislike us so heartily." McKittrick explained, "The situation will need to be handled skillfully." And indeed, it was, at least from the point of view of the BIS, which survived, and its former president, who was now working for Aldrich.[3] Harriman, the man at the other end of the line, was also a prominent banker and a diplomat who had served as US ambassador to London and Moscow. Harriman was now one of the most powerful men in the world, in charge of the Marshall Plan, the $12 billion American aid program to reconstruct postwar Europe. Harriman asked McKittrick if he could be in Paris to start work on June 2. Yes, gladly, replied McKittrick.

TWO MILLENNIA AGO, the Roman philosopher Cicero observed, "The sinews of war are infinite money." An updated version of his epithet would note that "the sinews of war are the transnational flow of infinite money," which will find its way around any obstacle. When the Allied leaders met at Potsdam in August 1945, they agreed that the German economy would be decentralized and the power of the cartels broken up. But the Nazi industrialists had no fear of such threats—Thomas McKittrick, as the OSS Harvard Plan documents show, had already reassured them that even if decartelization took place, the Allies would still guarantee their profits.

By the time Harriman summoned McKittrick to Paris, it had long been decided in Washington that the German business elites would not be punished. The Morgenthau Plan, which called for Germany to be stripped of its industrial might and turned into a pastoral state, had been so watered down by General Lucius Clay, the American commander of occupation forces, that it was meaningless. (Clay had set up shop in Frankfurt at the former headquarters of IG Farben, whose buildings had mysteriously escaped Allied bombing.) Washington's JSC Directive 1779, passed in the summer of 1947, institutionalized this

change in policy. German industry would be rebuilt; its steel mills and forges would once again be the powerhouse of Europe.

What would be the role of the BIS in the German renaissance? After 1945, the bank had no reason to exist. The BIS had been founded to manage German reparations payments, and none had been paid since the early 1930s. The BIS claimed it was needed as a meeting place where central bankers could gather to coordinate monetary policy. But as commercial airlines expanded their networks across the world, the BIS's lush hospitality could easily be replicated in a hotel or conference room in London, Paris, Wall Street, or anywhere else the bankers wished to gather. The BIS said it was needed to help coordinate the postwar global economy. The new institutions of the IMF and the World Bank had been founded for precisely this reason. Unlike the BIS, the IMF and World Bank were not Nazi collaborators.

The Basel bankers had also lost their golden touch. For the first time, in 1946, the BIS registered a loss. The founders could not help. Montagu Norman, now in his midseventies, had retired from the Bank of England. Raised to the peerage as Baron Norman of St. Clere, his legacy endured, and he remained influential, but he could no longer move markets with a sentence or two. Nor could Hjalmar Schacht provide assistance to the bank he had once proudly called his own. Schacht had been arrested after the July 1944 plot against Hitler and sent to Dachau concentration camp. He survived and was liberated by the US Army. He was then arrested and put on trial at Nuremberg and charged with organizing Germany for war, which is precisely what he had done. Unbowed by the weight of the proceedings, Shacht and his lawyers were putting up a spirited defense, aided by his sporadic instances of public opposition to the Nazis during the 1930s.

Yet, ultimately, no matter how tainted its reputation, Norman and Schacht's creation would prove as durable as they had hoped. Throughout the war, the repeated arguments of BIS officials that the bank must keep working so that it could play a central role in the reconstruction of postwar Europe had found a ready audience among both the Allied and Axis leadership. Bureaucratic inertia also helped the BIS. The general sentiment in both Washington, DC, and London was that the bank could be useful and was too complicated to dismantle. The BIS was "built to last," argued British Treasury officials. It was both a Swiss corporation and an international organization protected by its own treaty. Britain had just won a war, and there were other priorities for scarce resources. Lord Catto, the new governor of the Bank of England, also came to the BIS's defense: The IMF was completely new, and who knew how effective it would be? The BIS, in contrast had existed for fifteen years and was staffed by experts. Postwar Europe, like prewar Europe, still needed a place for pan-European meetings of central bankers. Basel remained the ideal venue.

BUT BEFORE A cent of Marshall aid could be sent to Europe, the plan had to be approved by the US Congress. Harriman set up a bipartisan committee of political, labor, and business leaders to steer the plan through the US government and persuade American public opinion that it was in their best interest to send tax dollars to the war-ravaged continent. The committee's members included Owen Young, the architect of the last German reparations program, whose own eponymous plan had set up the BIS, and, of course, Allen Dulles, who saw the Marshall Plan as a means of dealing the death blow to the spread of Communism in western Europe. Barely a few months after the war ended, Allen Dulles was already demanding imports of food and raw material to rebuild German industry. He condemned the arrest and detention of one hundred thousand Nazis. "We find ourselves in the concentration camp business on a large scale," he told the Foreign Policy Association in January 1946, as though the German detainees who were fed, clothed, and received medical treatment from the Allies were about to dispatched to the gas chambers.[4]

In July 1947, soon after General Marshall announced his plan, the Conference for European Economic Cooperation (CEEC) met in Paris to work out how it would be implemented. The State Department made it clear to its European allies that American aid would come at a price: financial and economic cooperation between the recipient countries with a view toward eventual European union. The first step was to replace bilateral trade deals and exchange controls with multilateral policies. The following year, the CEEC was institutionalized as the Organization for European Economic Cooperation (OEEC), which still exists today as the Organization for Economic Cooperation and Development (OECD).

The OEEC's mandate was, essentially, to ensure that the State Department's plan for Europe, and, especially Germany, was implemented. It was charged with promoting economic and political cooperation between its members; developing intra-European trade by removing barriers and tariffs and studying the feasibility of customs unions, free trade, and multilateral payments.[5] The Marshall Plan was administered by another new agency, the European Cooperation Administration (ECA), which is where Thomas McKittrick worked. McKittrick arrived in Paris for the first ECA meeting on June 2, 1947. Conditions did not meet the standards of the BIS, he recalled. "The American embassy let us have a room and secretary. But the room didn't have any carpet on the floor and [only] the barest of bare furniture and we sat there."[6] There were twelve people present, and Harriman instructed each as to his responsibilities. McKittrick's was "Trade and payments." The dozen officials had no office, no organization, and no support staff. But they did have $5 billion in the bank, which they had to distribute quickly—and McKittrick no longer had to worry about Henry Morgenthau and Harry Dexter White.

Morgenthau had stepped down as Treasury secretary in 1945 and was now largely retired from public life. He devoted himself to Jewish causes and helping the new state of Israel. White left government and joined the IMF as its first US executive director. He was an idealist as well as a realist. He saw the IMF as a means to promote economic growth through trade and financial stability. White, like the BIS, believed in global financial cooperation as the path to prosperity—but crucially, a cooperation coordinated among governments rather than unelected central bankers and technocrats.

After 1945 White was subjected to sustained attacks on his patriotism, attacks that James M. Boughton, the IMF's official historian, has described as ranging from "the questionable to the bizarre."[7] White's failed attempt to bring the Soviet Union into the IMF in 1944 (when the country was an ally of the United States) and his meetings with Soviet officials were recast as support for Communism. So was his support for the Morgenthau Plan to de-industrialize Germany. White's request to the nationalist government in China to account for how it had spent hundreds of millions of dollars in American aid was respun as sympathy for Mao Tse-Tung's Communist forces. In August 1948, White was called to testify before the House of Representatives Committee on Un-American Activities to be questioned about his relations with the Soviets. Historians continue to investigate these. There is evidence that White passed sensitive information to Moscow. Decrypted Soviet diplomatic cables from the 1940s detail White's discussions of American foreign policy with a Soviet official. But an authoritative biography of White by Bruce Craig argues that White was regarded by Moscow as a "trusted individual" rather than an active agent.[8] Certainly White's influence on policy making and access to high-level governmental decision making made him a person of great interest to the Soviets. Whether White was an agent or an asset, he was passing sensitive information to a hostile foreign power. Craig argues that White was a Rooseveltian internationalist, who believed in the need for cooperation with the Soviets, rather than a Communist.[9] Either way, such views were no longer acceptable in Washington in the late 1940s.

White suffered from heart trouble. His appearance before the committee was highly stressful. Three days later, he died.

MEANWHILE, THE BIS was swiftly building itself into the new global financial architecture. That September 1947 bank officials in charge of protocol and hospitality were in overdrive. The BIS was preparing for the two most important VIPs it had received since the end of the war: John McCloy, the president of the new World Bank, and Eugene Black, its executive director. There was little danger of discord: McCloy was one of the most influential advocates of normalization with Germany. Black was a former vice president of Chase National—the new employers of Thomas McKittrick. McCloy had deliberately sabotaged the Morgenthau Plan and steered President Roosevelt away from punishing Germany in favor of rebuilding German industry. As the website of the United States embassy in Germany notes, "He was instrumental in undermining the proposed 'Morgenthau Plan' for Germany which would have reduced the country to a land of forests and farms."[10]

The Marshall Plan was certainly a triumph for the prewar Wall Street–Berlin financiers. McCloy, Black, and Harriman all had extensive prewar financial interests in Nazi Germany, as McKittrick had. McCloy had been a partner in Cravath, a powerful New York law firm, which represented General Aniline and Film, IG Farben's American subsidiary.[11] Like his friend Allen Dulles, McCloy had been based in Paris in the prewar years where he ran the law firm's office. McCloy left Cravath in 1940 to serve as assistant secretary for war. This prevented a potentially ugly conflict of interest, for Cravath's clients also included the United States Alkali Export Association (Alkasso), which had intentionally deprived the United States of vital chemicals during the war.[12]

Alkasso was composed of the eleven most important alkali producers in the United States and handled their foreign trade. In 1936 Alkasso entered into a cartel agreement with Solvay & Cie, the Belgian chemicals company represented by John Foster Dulles, and Imperial Chemical Industries, a British combine. The cartel continued during the war, and in 1942 the Department of Justice launched an investigation into Alkasso, just as it had with Standard Oil. Standard Oil had restricted the United States' ability to produce artificial rubber. Alkasso prevented free trade in soda ash, a basic ingredient in vital war materials such as glass, textiles, and numerous chemicals.

In 1944 the Justice Department launched a civil lawsuit against Alkasso and ICI for breaching the Sherman Anti-Trust Act. Also named as co-conspirators were Solvay & Cie and IG Farben. Alkasso was charged with restricting exports and prohibiting imports, eliminating competition, and price-fixing. Cravath and Alkasso lost the case. The sixty-page decision, delivered by federal judge Samuel Kaufman, was blistering. It found that Alkasso had near total control of alkali imports and exports. Alkasso even ran its own network of inspectors at docks to examine materials leaving the United States. It compiled a blacklist of all competitive exporters and instructed its members not to sell to those on it. It forced its customers to give written assurances that they would not sell their products outside the United States. The cartel had continued during the war years, the decision, delivered in 1949, noted.[13]

McCloy was a ruthless, self-made man who was not known for his humanitarianism. On the contrary—the president of the World Bank had been instrumental in the internment of some 120,000 American citizens and residents of Japanese ancestry, causing an enormous amount of human suffering—a bitter legacy that still lingers today. Arguably, he had blood on his hands. McCloy used his office and influence over Henry Stimson, the secretary for war, to repeatedly block attempts by Jewish organizations to have the US Air Force bomb Auschwitz. By 1944 numerous testimonies of escapees and witnesses had reached Western capitals.[14] It was widely known among both governments and Jewish organizations that the camp was an industrial death factory. Allied bombers regularly overflew the complex and occasionally bombed the outlying IG Farben Buna factory at Auschwitz III and other buildings. It would have been comparatively simple to destroy the key railway junctions and gas chambers. In August 1944, soon after 430,000 Hungarian Jews had been deported to Auschwitz, where most were gassed on arrival, A. Leon

Kubowitzki of the World Jewish Congress wrote to McCloy asking that Auschwitz be bombed. McCloy refused. He replied that such an operation would demand diversion of resources being used elsewhere and would be of "doubtful efficacy," an argument also echoed by British officials. McCloy also made the macabre claim that bombing Auschwitz might "provoke even more vindictive action by the Germans," although it is hard to imagine what could be more vindictive than the industrialized extermination of thousands of people per day.[15]

Eugene Black, McCloy's colleague at the World Bank, had joined Chase National in 1933 as vice president. He was promoted to senior vice president in charge of the bank's investment portfolio. This was substantial: at that time, Chase National was the world's largest bank in terms of assets, which is why it was so appreciated by Nazi Germany.

Averell Harriman's financial links with Germany also stretched back decades. Soon after the end of the First World War he had set up his own bank, W. A. Harriman, which carried out extensive business in Germany. Together with Lee, Higginson—the former employers of McKittrick—W. A. Harriman bank lent $20 million to the Berlin City Electric Company, with legal work provided by John Foster Dulles. Harriman was a board member of the International Chamber of Commerce (ICC), as was Thomas McKittrick. The chamber's president, after 1937, was Thomas Watson, the boss of IBM who had traveled to Berlin to be awarded the Merit Cross of the German Eagle by Hjalmar Schacht and whose Hollerith machine was used by the Nazis to speed up the organization of the Holocaust.

Harriman was an early enthusiast for transnational finance. During the mid-1920s he attended an ICC meeting in Paris, the only American of any prominence present. He later recalled,

> *One evening I remember that I met with the leading bankers and industrialists of the principal countries. I remember the British and German, the French—I can't remember who else was there. It was quite a small dinner—it was a private dinner. Yet, they took the International Chamber of Commerce more seriously than we did and there were some important men present. I asked them why they thought that the United States was moving ahead as we were in the mid-twenties, you remember, whereas Europe was stagnant with built-in unemployment. They said it was because we had a continent of free trade.*[16]

Sometime in the early 1920s, Harriman had traveled to Berlin and met Fritz Thyssen, the powerful German industrialist, according to declassified US documents. Thyssen became one of Hitler's most influential backers and persuaded many of his fellow businessmen to support the Nazis, until he fell out with Hitler after Kristallnacht and fled Germany. Thyssen told Harriman that he wanted to set up a bank in New York to look after his interests in the United States. In 1924, W. A. Harriman duly set up a new bank for Thyssen called the Union Banking Corporation (UBC). UBC had seven directors, including E. Roland Harriman, his brother, and Prescott Bush, the grandfather of President George H. W. Bush, and great-grandfather of George W. Bush. But UBC was not a bank in the normal sense of the word. It was a front for Bank Voor Handel en Scheepvaart, based in Rotterdam in the Netherlands. Bank Voor Handel en Scheepvaart was wholly owned or controlled by the Thyssen family, US investigators believed.

In 1931 W. A. Harriman merged with Brown Brothers & Co., to form Brown Brothers Harriman (BBH) with offices at 59 Wall Street, a few doors from Sullivan and Cromwell, which was at number 48. The UBC was highly successful. US investigators believed that between 1931 and 1933 UBC bought more than $8 million worth of gold, of which $5 million was sent abroad, probably to Germany.[17] This is why, on November 6, 1942, the US Alien Property Custodian issued vesting order 248 and seized all four

thousand shares of UBC and its assets.[18] Harriman, who was traveling the world as President Roosevelt's special envoy to meet with Churchill and Stalin, continued his diplomatic career unhindered. The month after UBC was vested, Joseph Ripley, one of Harriman's oldest and closest business associates, represented Brown Brothers Harriman at McKittrick's dinner at the New York University Club.

WITH CREDENTIALS SUCH as these, McCloy's and Black's visit to the BIS could only be a success. The BIS, its officials pointed out, had much to offer. It was the world's oldest global financial institution. It had unrivaled experience in gold and currency swaps and superb technical expertise. Its annual reports were universally regarded as the single most useful source of financial and economic information. The BIS agreed to host the World Bank's European mission and to provide it with technical support. Soon after, when the World Bank issued its first non-dollar bond, the BIS negotiated the bond's sale to Swiss banks and bought a substantial share for its own account.

It seemed only natural that when the CEEC, the committee in charge of Marshall Plan payments, formed a subcommittee to manage multilateral payments between France, Italy, Luxembourg, the Netherlands, and Belgium, the BIS would be at the center of the new system. Frederick Connolly, a veteran BIS official who had formerly worked at the Bank of England with Montagu Norman, drafted an agreement on multilateral payments, which was signed in Paris in November 1947. The BIS was appointed agent in charge of executing the transfers. The bank hosted a conference for the five signatories and observers from Switzerland, Britain, and the US Treasury and State Departments. A resolution was passed encouraging central banks to use the BIS to settle their payments, rather than doing so directly between creditor and debtor. It also requested that the BIS be informed of any direct transactions.

At first glance, the Paris accord on multilateral payments seems an obscure footnote to postwar economic history. Monetarily, it was almost irrelevant. By the end of 1947, only $1.7 million of $762.1 million outstanding balances between the five signatories had been settled. But this little-known accord was, in fact, highly significant. An important precedent had been set: transactions between central banks would now go through Basel, rather than between national treasuries. Only the BIS had the staff and the expertise, dating back to its experience managing reparations payments in the 1930s, to manage an effective system for intra-European payments. The BIS had effectively reasserted itself as an international clearinghouse for Europe's central banks.

Emboldened by the new payments system, the technocrats and Euro-federalists were now on the rise. Belgium called for a customs union between the Benelux countries and France and Italy. Italy went one better and proposed a customs union between all countries receiving aid under the Marshall Plan, as a step toward European Union.

The postwar blip in the BIS finances was short and temporary. By 1951, the BIS was once again paying dividends to its shareholders. BIS observers attended IMF and World Bank meetings. The bank enjoyed a cordial relationship with the New York Federal Reserve, thanks in part to the legacy of Leon Fraser, the former BIS president who had also served as a director of the New York Fed. (Despite his successful career, Fraser suffered from severe depression. In April 1945 he shot himself in the head with a revolver and died on the way to the hospital.)

THE BRETTON WOODS motion calling for the dissolution of the BIS, and the campaign against the bank led by Henry Morgenthau and Harry White had been the most serious threat yet to the BIS's existence. Although the full details of the bank's role as a channel between the Allies and the Axis were not yet public in the immediate postwar years, the BIS was thoroughly tainted by its acceptance of Nazi

gold and its cozy relationship with the Reichsbank. But the bank proved more nimble and agile than its foes. Its managers deftly immediately built the BIS into the new global financial architecture. The BIS did not seek to compete with the IMF and offer loans to indebted countries (although it would later arrange international credits to troubled economies). Nor did it try and compete with the World Bank and fund development projects. Rather, the BIS stuck to what it knew best: offering discreet services, financial coordination, and a confidential venue to central bankers, all of which were in great demand in postwar Europe.

The bank's excellent connections with American policymakers such as Allen Dulles and John McCloy brought an early understanding of Washington's commitment to a new, united Europe. The drive was now unstoppable, with wide political support across European capitals. Such a project, the BIS managers understood, would offer immense new opportunities for the bank over the coming decades. The new Europe would need swift, international payment mechanisms, more harmonized exchange rates, and perhaps eventually a new single currency. There was nobody better placed to offer these services than the technocrats of the BIS.

When detained in Dustbin, among a number of references to the financially great he pointed out that the President of the BIS, Mr. McKittrick of the United States, would be able to speak favourably of him.

— British intelligence report on Hermann Schmitz, CEO of IG Farben, while held prisoner at Kransberg Castle, aka "Dustbin," December 1945[1]

While Hermann Schmitz was dropping Thomas McKittrick's name in the hope that the BIS president might somehow spring him from prison, Rudolf Brinckmann was also plotting how to keep his wartime profits. The German banker, who would soon be appointed a director of the BIS, was locked in a bitter dispute with the Warburgs over the ownership of Brinckmann, Wirtz and Company, in Hamburg, the successor to M. M. Warburg bank, which had been Aryanized by the Nazis.

Brinckmann had joined M. M. Warburg in 1920 and worked as the office manager. He spoke six languages and was seen as loyal, dependable, and trustworthy. The Warburgs joked that Brinckmann was their "in-house Aryan," even though he was actually Mediterranean looking, because of his Greek-Turkish background. M. M. Warburg was then one of the world's most influential banks, the centerpiece of a financial dynasty whose name was a byword for stability and prudence. The family trusted Brinckmann absolutely, so when the Nazis took power in 1933, he was granted full power of attorney and took the place of the members of the Warburg family on other company boards. Five years later, when the bank was Aryanized, Brinckmann, together with Paul Wirtz, was made a director, on the understanding that he would look after the Warburgs' interests.

Brinckmann's wartime record was ambiguous. He had hired Nazi party loyalists and purged the last remaining Jewish employees. Staff began to wear Nazi party insignia. Brinckmann wrote letters to former clients, pointing out that now that the bank had been Aryanized there was no reason not to come back, the letter usually ending with "Heil Hitler."[2] He traveled to Essen to win back the account of the Krupp family of industrialists, who were one of Hitler's most important backers. Brinckmann renamed the bank after himself, and he also negotiated the release of fourteen members of the Warburg family and employees from Nazi-occupied Amsterdam, who eventually reached the United States.

After the war numerous German bankers, including Brinckmann, were placed under house arrest. But the Warburgs, grateful that their bank still existed, albeit in another form and under another name, helped Brinckmann as much as they could. They provided a supply of food. His house arrest was lifted. They got him a place on a de-Nazification tribunal—an immensely influential position. Brinckmann initially offered to return the bank to the family, but as the full horror of the Holocaust became public, the Warburgs declined, ambivalent about their return to Germany.

Brinckmann was soon glad that his offer was refused, because the bank was profitable. Soon after, some of the Warburgs, including Eric, decided to settle in Germany and asked for their bank to be returned. Brinckmann refused. Like many German owners of formerly Jewish concerns, he rewrote history. The 1938 transfer into his name was not an Aryanization, he claimed. Rather, he had saved the remnants of a collapsed bank. The Warburgs should be grateful to him, rather than vice versa. He offered the family a ten percent ownership stake. That was unacceptable, said the family. If it had not been for M. M. Warburg, Brinckmann, Wirtz and Company would not exist. It was built on the ruins of the Warburg

empire and even operated out of the same building. The two sides finally agreed that the family would take 25 percent, with a five-year option on 50 percent.

Brinckmann joined the BIS board of directors in 1950, after the Warburgs put his name forward. But if the Warburgs hoped that trips to Switzerland, the BIS's famed hospitality, and the inside information gleaned at the bank's lunches and dinners would mollify Brinckmann, they were quickly disappointed. The BIS, it seemed, had gone to Brinckmann's head, and he remained as stubborn as ever. Eric Warburg, a prominent member of the Jewish banking dynasty, dubbed the new BIS board member "John Foster Brinckmann," after John Foster Dulles, the ruthless lawyer turned Cold War warrior who was soon to be appointed secretary of state. Sigmund Warburg wrote to Eric in 1950, "During the last few years I've found Brinckmann extraordinarily arrogant and egotistical, but during my last discussion in Hamburg I found that his arrogance and his egotism had gradually reached a point where they are scarcely bearable any longer."[3] There seemed no end in sight to the dispute.

DESPITE THE MARSHALL Plan, postwar Germany was devastated, its population barely scraping a living. A fifth of all housing stocks had been destroyed, food production was about half of its prewar levels, and industrial output in 1947 was one-third of its 1938 level.[4] Basic goods were rationed, and wages and prices were controlled. The black market was thriving, and there was no properly functioning central bank. Officially, the Reichsbank had ceased to exist. The Reichsmark staggered on, still in circulation, although the main unit of currency was American cigarettes.

In 1948, everything changed. The Reichsbank was abolished completely and replaced by the Bank deutscher Länder (BdL). The deutschmark replaced the Reichsmark. The BdL was a national clearinghouse for the banks of the German regional states in the western occupation zone, modeled broadly on the US Federal Reserve. Unlike the Reichsbank, which had been brought under government control, the BdL, which would now represent Germany at the BIS in Basel, had its independence constitutionally guaranteed.

Hjalmar Schacht was not impressed with the deutschmark. It was backed neither by gold nor by foreign currency reserves. It was a fiat currency, imposed by the Western authorities. Schacht told Wilhelm Vocke, the president of the new German national bank, that the deutschmark would collapse in six weeks. But Schacht was wrong. The deutschmark was backed, and by assets even more powerful than gold or foreign exchange: public confidence and postwar planning by the Nazi leadership.

At the same time, Ludwig Erhard, the economic director of the British and American occupation zones, lifted price restrictions and controls. The results were spectacular. Employment soared, inflation plummeted, the economy boomed. The deutschmark was stable and enjoyed the public's full confidence. The western powers and their German subordinates proclaimed the dawn of a new era.

But the new central bank, currency, and Germany's economic recovery were all deeply rooted in the Third Reich. Because German companies, especially armaments firms, had reinvested their massive profits, despite the Allied bombing campaign and reparations, Germany's capital stock—its productive equipment, buildings, infrastructure, and other assets—was actually greater in 1948 than in 1936.[5]

The lines of financial continuity between the Third Reich and postwar Germany reached right to the top. The BdL's first president, Vocke, was a Reichsbank veteran and ally of Hjalmar Schacht. Wilhelm Vocke had sat on the Reichsbank board from 1919 to 1939 and was Germany's alternate member on the BIS board from 1930 to 1938. He would now return to Basel for the governors' meetings. Vocke remained loyal to his former boss and testified at Schacht's trial at Nuremberg. He made the unlikely claim that Schacht had believed Germany's weapons buildup was intended to support a policy of armed neutrality and to reduce unemployment.[6] Vocke, however, had not joined the Nazi party, unlike many of

his colleagues at the BdL. Every state institution in postwar Germany—the police, judiciary, civil servants, teachers, doctors, and the intelligence services—relied on former Nazis to function. But the continuity among the bankers was striking. Between 1948 and 1980, 39 percent of officials on the executive and governing boards of either the BdL, the central banks of the regional states, or the Bündesbank (the BdL's successor) were former Nazis.[7]

Some, such as Fritz Paersch, had been important figures in Hitler's economic empire. Paersch was the mastermind of the Nazi plunder and despoliation of Poland. As president of the central bank in German-occupied Poland, he reorganized the currency. Without his work, the Nazi occupation would not have been able to function economically. Hans Frank, the governor general of Poland who oversaw the murder, enslavement, and deportation of millions of Poles and Polish Jews was a great admirer of Paersch. Frank was found guilty of war crimes at Nuremberg and executed. And Paersch should have been put on trial as well, but instead he lived freely and applied for a senior position at the BdL. He was rejected because of his wartime past but was compensated with a position as vice president of the Hesse state central bank, where he worked until 1957. Paersch then found a new sinecure: as official liquidator of the Reichsbank, whose legal affairs still stuttered on.[8]

Like Schacht during the 1930s, Ludwig Erhard, the economic director of the western occupation zones, was hailed as a miracle maker. The truth was more prosaic. Erhard, a future chancellor of West Germany, was an ambiguous figure. He had refused to join any Nazi party organizations and was connected to the German resistance. But Erhard had accepted funds from the Reichsgruppe Industrie, the organization of German industrialists, including IG Farben, that supported Hitler. He was awarded the war service cross for his work on economics. By 1943 Erhard's work had come to the attention of the German bankers and industrialists who realized that the war was lost. They formed two groups to prepare for the future and ensure their continuing economic power in the postwar world: the Committee for Foreign Economic Affairs, composed of financiers and industrialists, and the Small Working Group, composed solely of industrialists, including Hermann Schmitz, the CEO of IG Farben and BIS director.[9] Erhard was the connection between the two groups.

The members of the Committee for Foreign Economic Affairs included Hermann Abs of Deutsche Bank, the most powerful commercial banker in the Third Reich. The dapper, elegant Abs was an old friend of the BIS. He had been sent there by Schacht during the 1930s to try and stall demands for repayments of the loans that financed Germany after 1918.[10] In Basel, Abs frequently met with a British banker called Charles Gunston, who was a protégé of Montagu Norman. Gunston managed the Bank of England's German desk, which made him immensely important during the 1930s. Gunston was so keen on the new Germany that he spent his 1934 summer holidays at a work camp for enthusiastic Nazi party members.[11] He also admired Abs and later described him as "Very urbane. Always a velvet glove around an iron fist." Abs did not join the Nazi party, but he was so essential for the functioning of the Third Reich's economy that he did not need to. As the head of Deutsche Bank's foreign department during the war, Abs was the lynchpin of the continent-wide plunder, directing the absorption of Aryanized banks and companies across the Third Reich. During the twelve years of the Third Reich, the bank's wealth quadrupled. Abs sat on the board of dozens of companies, including, naturally, IG Farben.[12]

In 1943 the Nazi industrialists asked Erhard to write a paper on how German industry could be converted back to peacetime production. Erhard argued for a free and competitive market with a gradual elimination of state controls. German industry would be redirected, as quickly as possible, to producing consumer goods.[13] Erhard was taking a substantial risk by putting his name to such thoughts: any postwar planning that assumed that Germany might lose the war was enough to send the author to a concentration camp.

But Erhard had protection at the highest levels of the Nazi state: Otto Ohlendorf, the chief of the SS internal security service. The SS was a business as well as a killing machine, the state engine of looting, plunder, and despoliation, from the gold extracted from the teeth of concentration camp victims to the banks, steelworks, factories, and chemical plants of Nazi-occupied countries. Ohlendorf had extensive firsthand experience of the SS's methods. Between 1941 and 1942, Ohlendorf had commanded Einsatzgruppe D, the extermination squad operating in southern Ukraine, which had murdered ninety thousand men, women, and children. Ohlendorf, an intelligent and educated man, showed great concern for the psychological welfare of his squad's gunmen. He ordered that they should all fire at the same time at their victims, so as to avoid any feelings of personal responsibility.

Ohlendorf also held a senior position at the Ministry of Economics, supposedly focusing on Nazi Germany's foreign trade. By 1943, after the Russian victory at Stalingrad, Ohlendorf also understood that the Third Reich would eventually lose the war. His real job was to plan how the SS would keep its financial empire so that Germany would reassert its economic dominance over Europe after the inevitable defeat. The postwar priority was rapid monetary stabilization, to preserve economic stability and avoid Weimar-style hyperinflation. Germany would need a new currency, which would have to be imposed by the occupying powers, as well as a mixed economy of state and private sectors. There was an obvious overlap with Erhard's ideas. Ohlendorf came to hear of Erhard's work, and Erhard was persuaded to send him a copy of his memo.

As the Allies advanced on Germany, the Nazis stepped up their plans for the postwar era. On August 10, 1944, an elite group of industrialists gathered at the Maison Rouge Hotel in Strasbourg, including representatives of Krupp, Messerschmitt, Volkswagen, and officials from several ministries. Also in attendance was a French spy, whose report reached the headquarters of the Allied invasion force, from where it was forwarded to the State Department and the Treasury. The account of the meeting is known as the Red House Report.

Germany had lost the war, the Nazi industrialists agreed, but the struggle would continue along new lines. The Fourth Reich would be a financial, rather than a military imperium. The industrialists were to plan for a "postwar commercial campaign." They should make "contacts and alliances" with foreign firms but ensure this was done without "attracting any suspicion." Large sums would have to be borrowed from foreign countries. Just as in the prewar era, the US connection and links to chemical firms, such as the American Chemical Foundation, were essential to expanding German interests. The Zeiss lens company, the Leica camera firm, and the Hamburg-American line had been "especially effective in protecting German interests abroad." The firms' New York addresses were passed around the meeting.

A smaller group attended a second, select meeting. There the industrialists were instructed to "prepare themselves to finance the Nazi party, which would be forced to go underground." The prohibition against exporting capital had been lifted, and the government would help the industrialists to send as much money to neutral countries as possible, through two Swiss banks. The Nazi party recognized that after the defeat, its best-known leaders would be "condemned as war criminals," the intelligence report concluded. However, the party and the industrialists were cooperating in placing the most important figures in positions at German factories as research or technical experts.[14]

US Treasury officials were closely watching this massive export of German capital, much of which was going to South America. Funds were pouring out of Germany and other Nazi-controlled territories, Harry Dexter White told a meeting of Treasury officials in July 1944 during the Bretton Woods conference. Nazi leaders were preparing to flee the country or have their property confiscated. "They bought estates and industries and corporations, and there is evidence that the German corporations have been buying into South American corporations in the expectation of being able to re-establish themselves

there after the war."[15] The cloaking operation was extremely complex, said White. "They are working through first, second and third fronts, so it is pretty hard to trace it without having all the data available." The Treasury officials also discussed the BIS at the same meeting, noting that out of twenty-one board members and senior officials, sixteen were "representatives of countries that are either now our enemies, or are occupied," including Walther Funk and Hermann Schmitz.[16]

Emil Puhl discussed the Nazi leadership's postwar strategy with McKittrick at the BIS in March 1945, during the last few weeks of the war. The information he passed to McKittrick echoes that included in the Red House Report and Harry Dexter White's discussion at Bretton Woods. Military defeat was merely a temporary setback. The Nazis were fanatics and would never give up their ideals, Puhl explained. Instead they would go underground. McKittrick immediately informed Dulles of the conversation. Dulles sent the information on to London, Paris, and Washington on March 21, 1945. His telegram noted that Puhl had "just arrived" in Basel:

> *He said that the jig was up but that Nazis had made careful plans to go underground, that every essential figure had his designated place, that Nazism would not end with military defeat as Hitler and his fanatical followers would no more change their philosophy than would Socrates or Mohammed, that these men were just as convinced of their cause as ever and carried a great body of people with them. He emphasized that Nazism was like a religion, not merely a political regime.*[17]

After the Allied victory, Donald MacLaren, the British intelligence agent who had brought down GAF, IG Farben's US subsidiary, was sent to Berlin to investigate the chemicals conglomerate. MacLaren wrote an extensive dossier on IG Farben, its history and key personnel, and its central role in preparing and waging war. MacLaren laid out in detail how IG Farben's trading partners in New York and London, such as Standard Oil, had willingly entered into cartel arrangements with the chemical conglomerate, thus ceding control to Germany and helping it to re-arm.

SO WHAT THEN should be the fate of the Nazi industrialists such as Hermann Schmitz? For MacLaren, the answer was clear. Schmitz had murdered, enslaved, and plundered from behind his desk, rather than on the battlefield. He was a war criminal as much as the leaders of the SS and should face the same punishment. But not all Allied officials agreed. When MacLaren asked his superiors if the industrialists were to be included with the Nazi military leadership as war criminals, he was told, "The term 'industrialists' raises a point on which no definite line has been laid down."[18] Schmitz, as MacLaren noted, certainly believed himself to be protected by his connection to the BIS and to Thomas McKittrick.

At one stage it seemed justice might be done. In 1947, twenty-four IG Farben executives, including Schmitz, were put on trial at Nuremberg. Twelve were found guilty. The sentences were derisory. Schmitz was sentenced to four years. Georg von Schnitzler, the commercial chief, who had apparently used the BIS to contact the Allies, received five years. Otto Ambros, a senior manager of IG Auschwitz, received eight years. Ambrus testified that the prisoners at IG Auschwitz were fortunate to "have been spared all that which happened" in the main concentration camp. The IG managers had also saved them a commute. The slave laborers could live on-site and no longer had to march fourteen kilometers a day to and from the main camp. "There was no stinting when Monowitz was built. It was heated and hygienic," Ambrus explained, although Rudy Kennedy, who worked as a slave laborer for IG Farben when he was a teenage boy, remembered conditions rather differently. The slave laborers were served soup at lunchtime,

soup with a "higher calorific content" than most Germans enjoyed in the immediate postwar years. "I believe that IG Farben and its officials deserve not a reproach, but due recognition," Ambrus later wrote, and they would soon get it.[19]

IG Farben was broken up into four successor companies: BASF, Bayer, Hoechst, and Cassella. The dismantling was no punishment. The shareholders asked the occupation authorities to transfer the conglomerate's assets to the successor firms, and they agreed. BASF, Bayer and Hoechst immediately reconstituted themselves, with the same staff working in the same offices and factories. A new holding company was created to deal with the legal fallout and consequences of the breakup. The legacy firms said they had no obligations for IG Farben's sins, as they had not legally existed during the war. It was a shameless and completely successful legal maneuver.

In 1949 John McCloy left the World Bank and started work as US High Commissioner for West Germany. McCloy, the former partner in the Cravath law firm that had represented GAF, the American wing of IG Farben, did not forget his former business partners. Hermann Schmitz was released from prison in 1950, and by February 1951 all of the IG Farben executives were free. McCloy also freed Alfried Krupp. The Krupp industrial empire had worked about eighty thousand slave laborers to death in a network of fifty-seven labor camps guarded by the SS. Krupp was sentenced to twelve years imprisonment, but he served less than three.

Otto Ohlendorf, the former commander of Einsatzgruppe D and protector of Ludwig Erhard, was an exception. He was hanged. But McCloy ordered that Nazi camp doctors who had conducted experiments on inmates, Nazi judges who had dispensed Gestapo justice, and SS officers who had organized mass killings be freed or have their sentences drastically reduced.[20] Seventy-four of the 104 defendants convicted at Nuremberg had their sentences substantially reduced, and ten death sentences were commuted.[21] Heinz Hermann Schubert, Ohlendorf's adjutant, who had personally supervised a mass execution of seven hundred people at Simferopol, had his death sentence commuted and was sentenced to ten years in prison.

The IG Farben managers were swiftly welcomed back into the German business community. Hermann Schmitz joined the supervisory board of the Deutsche Bank. Otto Ambros, provider of soup to slave laborers, joined numerous company boards and set up as an economic consultant. His clients included Konrad Adenauer, the federal chancellor. Kurt von Schröder, the banker and BIS director who had brokered Hitler's rise to power, was found disguised as an SS corporal in a POW camp in France. He was tried by a German court for crimes against humanity and was sentenced to three months in prison. Walther Funk, the dissolute Reichsbank president and BIS director, was found guilty of war crimes and sentenced to life imprisonment. The trial established how Funk had worked with Himmler, the SS chief, to ensure that gold and valuables from camp victims were credited to a special account at the Reichsbank in the name of "Max Heiliger" for the SS. Funk was released from Spandau prison for health reasons in 1957 and died three years later. Emil Puhl, Funk's deputy, BIS director, and friend of Thomas McKittrick, was also convicted of war crimes. Sentenced to five years, he was released in 1949.

Ironically, it seems the Warburgs were also instrumental in the reconstruction of German industry, thanks to the family's friendship with McCloy. Freddie Warburg had persuaded McCloy to take the position of president of the World Bank. The two men had known each other since the 1920s when McCloy had done legal work for Kuhn, Loeb, a branch of the Warburg empire. When Eric Warburg and McCloy dined together in August 1949, Warburg pleaded with McCloy to stop the dismantling and destruction of German industrial plants. Soon after, Warburg gave McCloy a list of ten steel, gas, and synthetic rubber concerns, including the Thyssen steel works and the Krupp gas works, to be saved. All were spared.[22] McCloy occasionally took a moral stand—he repeatedly told Germany to return Jewish

property. When he was informed that Germans who served on de-Nazification boards were being shunned as traitors, he ordered state governments to guarantee such people civil service jobs.

As for Schacht, charged with organizing Germany for war, he still had powerful friends in London and Washington. Green Hackworth, the legal adviser to the State Department, was working behind the scenes to help the former Reichsbank president. During the war, Hackworth had repeatedly sabotaged attempts to publicize Nazi war crimes and bring their perpetrators to justice, arguing that such moves would endanger American POWs.[23] Breckinridge Long, the assistant secretary of state, who had once praised Mussolini, supported Hackworth. Long and his aides had prevented Jewish refugees from obtaining visas, suppressed news of the Holocaust, and derailed attempts to document Nazi war crimes. In 1944 Henry Morgenthau's staff wrote a detailed paper that documented the State Department's wartime record. Its title was "Report to the Secretary on the Acquiescence of this Government in the Murder of Jews."[24]

Once again the Dulles connection came to the fore. In late 1945 Schacht requested that Hans Bernd Gisevius be summoned as a defense witness to testify on his behalf. Gisevius, the wartime German consul in Zürich, was also an officer in the Abwehr, German military intelligence, a member of the anti-Hitler resistance, and one of Allen Dulles's most important agents, known as OSS source 512. Declassified US intelligence documents show that Gisevius was expected to testify that Schacht had attempted to overthrow Hitler in 1938 and to talk about Schacht's difficult relationship with the Nazi party, so that Schacht could present himself as a member of the resistance.

The documents reveal how much effort the State Department made to get Gisevius, who was living near Geneva in Switzerland, to Nuremberg to aid Schacht. A telegram from US diplomats in Berlin to the State Department, on December 10, 1945, requests that the "necessary arrangements be made to bring him to Nuremberg on ten days' notice and that Tribunal be kept fully advised through this office."[25] Three days later, Leland Harrison, the US ambassador to Switzerland, cabled Washington that Gisevius was willing to appear as a defense witness for Schacht and could depart for Nuremberg any time in January on forty-eight hours' notice. Harrison asked the State Department to alert him when Gisevius should arrive in Nuremberg.[26] The US government, was, in effect, acting as an aide to Schacht's defense lawyer, arranging for Gisevius's transport and logistics, and coordinating his appearance with the Nuremberg Tribunal.

The US team at Nuremberg was split over Schacht. Robert Jackson, the chief US prosecutor, wanted to prosecute him. But his deputy, William Donovan, the former OSS chief, was opposed. Donovan argued that Schacht had been sympathetic to the Allies in the early years of the war. And there was the postwar German economy to consider, always a crucial factor in US policy calculations. A harsh cross-examination of Schacht would alienate the important German businessmen and financiers who favored good relations with the United States.[27] There was consternation in Washington when Schacht's lawyer told the press that Sam Woods, the US Consul General in Zürich, had offered the Reichsbank president a deal in 1939—that if he resigned from Hitler's government, he would be returned to power after the war. Considering all we now know about the secret back channels between the United States and Nazi businessmen, this seems highly plausible. Woods had long been a conduit between the US government and the Axis powers. After Admiral Horthy, Hungary's wartime leader who had permitted 430,000 of his own citizens to be deported to Auschwitz, was released from custody in 1946, Woods invited him to his wedding.[28]

The State Department's efforts on Schacht's behalf worked. He was initially found guilty but was then acquitted, to the fury of the Soviet judge. There were also suspicions that Montagu Norman had somehow managed to influence the proceedings through Sir Geoffrey Lawrence, the British judge. The British obsession with class seemed to play a part. Francis Biddle, the American judge, recorded in his diary that Lawrence had claimed Schacht was a "man of character" while other defendants were "ruffians."[29]

Norman was immensely relieved when Schacht was not hanged at Nuremberg, recalled his stepson, the writer Peregrine Worsthorne. "He did not think Schacht was guilty for the crimes of the war, but obviously being on speaking terms with any prominent Nazi made you a pariah after the war. He had made his mind up about Schacht before the war and the horrors." (In later years Priscilla Norman angrily denied that her husband had tried to influence the outcome of Schacht's trial.)[30]

Intriguingly, Worsthorne believes that Norman and Schacht managed to stay in communication during the war—if they did, the BIS would have been the natural channel. "Norman kept up this strange relationship that he had with Schacht, even during the war. Both during the First and Second World Wars the capitalist world was not at war. The bankers kept the system in cold storage. I am sure that there would have been absolutely no record of their contacts and that Norman kept in touch with him without the government knowing."[31]

After several more years of legal travails with the German authorities, Schacht was finally cleared of all charges. He started a lucrative second career as an investment adviser to countries in the developing world and set up his own bank, Schacht & Co. Schacht even visited Israel, albeit inadvertently when his airplane stopped briefly at Lydda airport in 1951. Schacht and his second wife, Manci, wanted to stay on board but were taken to the airport cafeteria to have breakfast. The Schachts handed their passports to the Israeli police and were photographed by reporters. His wife was too nervous to eat, so Schacht ate her breakfast as well. A waiter asked in German how "Herr President" had enjoyed his breakfast, using Schacht's Reichsbank honorific. The waiter told Schacht that he was from Frankfurt and missed his hometown. He asked for Schacht's autograph, which Schacht provided. The Schachts left Israel with no problems, although a furor erupted in the Knesset, the Israeli parliament, when the news broke that Hitler's banker had passed through the Jewish state without being arrested.[32]

"I say no permanent solution of the German problem seems possible without an effective European union.[1]"

— John McCloy, US High Commissioner for Germany, speaking in London in 1950

With the United States supplying the money through the Marshall Plan and the BIS providing the financial and technical expertise, the drive toward a united Europe was unstoppable. In October 1949, Paul Hoffman, the head of the ECA, which administered the plan, gave a definitive speech in Paris. He called for the expanding western European economies to integrate economically, set up a continent-wide free market, and to coordinate their "national, fiscal, and monetary policies."[2] This meant that governments should harmonize their spending and taxation as well as national interest rates: in other words, to move toward a United States of Europe.

Per Jacobssen, the BIS's influential economic adviser, agreed. Jacobssen believed the new European economies should be based on the free market. The era of autarky, state controls, and price restrictions was over. The ideal mix was an economy with about 80 percent in the private sector. The priority should be financial reconstruction and rebuilding trade and payments systems. Political and economic freedom would ensure prosperity, and welfare provision had to be made compatible with the market economy.[3]

Jacobssen also favored a federal solution for postwar Europe. During the war he had often met with Allen Dulles and British diplomats to persuade them of the merits of supra-nationalism, albeit with a maximum of power left at state level. In 1946 he went public with his idea. Jacobssen gave a talk at Gettysburg College in Pennsylvania with the grandiose title of "The Re-Education of Europe." The German problem could be solved only as part of the European problem. Postwar Europe would flourish through diversity, but a new loyalty was needed, one which superseded mere national fidelity.[4] Just as in the 1930s, the technocrats believed they knew best, although their ambitions were far more grandiose: the imposition of a new transnational financial, economic, and political structure, whether the people of Europe wanted it or not.

Marshall aid came at a price: remodeling European societies on the American model of consumerism and consumption. Hoffman's propaganda arm produced pamphlets, posters, leaflets, radio programs, and even traveling puppet shows that extolled the American lifestyle. The American dream—a house in the suburbs, a car, and numerous household appliances—was projected as a near-guaranteed benefit of American-style freedom.[5] The key to this was increased productivity on American-style production lines in a transnational free market.

For that to happen, and for the money to flow freely, new mechanisms of international payment had to be constructed, with the BIS at the center. This had started in 1947, when France, Italy, Belgium, the Netherlands, and Luxembourg had signed the Paris accord on multilateral payments, which was managed by the BIS. That was followed a year later by the Agreement for Intra-European Payments and Compensation, signed by sixteen European governments, the representatives of the French and British-American occupation zones of Germany, and the short-lived Free Territory of Trieste, which soon became part of Italy. The United States wanted the process to be speeded up. Washington pushed the European central banks to construct a comprehensive, multilateral payments system, recalled Alexandre

Lamfalussy, the BIS general manager between 1985 and 1993, demanding, "For the love of God stop being bilateral and start being multilateral."[6] Europe obeyed, swayed in part by a dedicated grant of $350 million of Marshall Plan funds to set up the European Payments Union. Established in 1950, at a single stroke the EPU removed the thicket of regulations governing European trade. EPU member states all agreed to accept each other's currencies for export payments. Bilateral balances were offset against a central fund, so all debts and credits were owed or received from the EPU. Eighteen countries signed up: all of Western Europe (excluding Scandinavia), Greece, Iceland, Switzerland, Britain, and Turkey. The BIS was appointed agent to the EPU. It managed its banking, kept its accounts, and controlled its funds.[7] The EPU "was the European Union of payments," said Lamfalussy. (The EPU applied to non-residents. Currency controls remained in place for residents.)

During the early 1950s Richard Hall worked at the Bank of England, helping to compose the briefing documents for the governor on his regular visits to the BIS. In 1955 Hall was seconded to the BIS to work on the EPU's monthly settlements and reports. There was no discussion about the BIS's wartime record, he recalled. "One of the BIS's finest achievements, for which it deserves no credit, was surviving the war. That was thanks to Maurice Frere, the Belgian banker who had lobbied hard for the BIS in Washington. He said that the BIS should not be got rid of because it might come in handy some time. Nobody in Basel was bothering their consciences about what the bank did during the war. It was the most sensible thing to do at the time. It was not a question of covering things up, it was really not high on anyone's list of priorities. They were trying to get on with the business of reconstruction and restoring the conditions so that trade and payments could now take place."[8]

The BIS itself remained ambiguous about the EPU. It regarded the multilateral payment mechanisms as slow and unwieldy.[9] The bank preferred free trade and currency convertibility. But, politically, the EPU was invaluable for the BIS. Thanks in large part to the EPU, the bank's future was assured. The BIS and the European integration project were locked into each other. The BIS was the only institution capable of handling the complicated technical processes demanded by economic integration. At each step on the road to a united Europe, the BIS would be there.

In 1951, France, West Germany, Italy, and the Benelux states signed the Treaty of Paris, establishing the European Coal and Steel Community (ECSC). The ECSC created a common market for coal and steel. This dry-sounding construct was, in fact, a profoundly significant development. The coal and steel market was now regulated by the ECSC's governing authority, which meant that the ECSC was a supranational institution, with regulatory powers over its members. For Jean Monnet, the architect and president of the ECSC, the new institution had transcended the old idea of the nation-state. The establishment of the ECSC set a pattern that would be followed for decades, one which still continues today. The removal of national sovereignty was always presented as an economic or technical measure, rather than the profoundly political process that it actually was.

Monnet was an early adopter of the idea of rule by technocrats. The French economist and diplomat was a veteran of the era that had brought forth the BIS: the post-1918 settlement. Born in 1888 to a family of Cognac merchants, Monnet worked for a while for the family firm, spending time in the City of London. During the war he coordinated British and French shipping to maximize their efficiency. In 1919 Monnet attended the Paris Peace Conference as an assistant to the French commerce minister. The carnage of the First World War had turned Monnet, like many of his generation, into a convinced internationalist. Monnet helped found the League of Nations and was appointed deputy secretary-general. But the League's slow and cumbersome decision making and the need to help his family business, which was in difficulties, pushed Monnet back to commerce.

Nowadays, Monnet is spoken of in reverential terms as the "Father of the Europe Union." Monnet's

ideas, which for many in Europe are now regarded as near-holy, have shaped our world and look set to do so for generations. His memory endures in buildings, scholarships, awards, and fellowships, including the Jean Monnet Center for International and Regional Economic Law and Justice at the New York University School of Law. Monnet's ideas have generated a whole new academic discipline: European integration studies. More than 785 universities in 72 countries offer the Jean Monnet Program, taught by 1,650 professors to 25,000 students a year.[10] But who were the formative influences on Monnet's thinking? The answer lies not in Paris, Brussels, or war-ravaged Europe, but in Wall Street, where Monnet worked during the 1920s and '30s.

Monnet's hidden history brings us back to some familiar and powerful names. Curiously—or perhaps not, considering the small world of the global financiers in the early twentieth century—Monnet was connected to John Foster Dulles and Sullivan and Cromwell; to John McCloy, then a partner in the Cravath law firm, which represented General Aniline and Film, IG Farben's American subsidiary, and even to Ivar Kreuger, the Swedish match king and con man.

Monnet met John Foster Dulles at the 1919 Paris Peace Conference, and the two men became close friends. They shared a similarly elitist view of the world, a disdain for democratic accountability, and an enthusiasm for making money. Dulles's extensive network of high-level contacts would prove extremely useful to Monnet over the next decades. During the 1920s, Monnet managed Blair & Company, an American finance house. Blair & Co. was represented by the Cravath law firm where John McCloy was a partner, and Monnet and McCloy became close friends. Blair & Co., like many investment houses of the time, was thoroughly corrupt and routinely carried out insider trading operations. Under Monnet's leadership, it kept a preferred list of fifty-eight clients who were brought in on profitable deals.[11] Monnet also worked with Dulles and several American banks, including Chase, on the stabilization of the Polish economy, which gave him an early understanding of the power of transitional finance to make or break a country's economy. When Blair & Co. was incorporated into the Bank of America, Monnet moved to San Francisco to run the new subsidiary. The firm's shares plummeted in the crash of 1929, and Monnet returned to Europe.[12]

After Kreuger, the Swedish match king and con man, went bust, John Foster Dulles sent Monnet to Stockholm to protect the interests of Kreuger's American creditors. In 1933, bored with Sweden, Monnet moved to China to help the government set up the Chinese Development Corporation, to develop communications and infrastructure. Monnet then returned to the United States and moved into a large apartment at Fifth Avenue and 92nd Street.[13] John Foster Dulles then suggested that Monnet—whom he described as "one of the most brilliant men I know" and "an intimate friend"[14]—go into business with another close friend of his, a banker called George Murnane.

In fact Monnet and Murnane had known each other since the First World War, when Murnane had worked for the American Red Cross in France. Murnane was a partner in Lee, Higginson—the Boston investment firm that had financed Kreuger and for whose London branch Thomas McKittrick worked. "I have long felt that they would make an ideal combination," Dulles wrote of Monnet and Murnane. The two men agreed to set up a new international finance house, using Dulles's legal services. At this time Sullivan and Cromwell was making so much money, especially from its business in Germany, that Dulles suggested the law firm invest in his friends' new company, Monnet, Murnane & Company. Sullivan and Cromwell put up $25,000, and Dulles invested another $25,000 of his own money.[15] Monnet focused on business in France and China, and Murnane looked after Solvay & Cie, the Belgium chemical firm that was a partner of IG Farben. Dulles was the lawyer for Solvay & Cie's American subsidiary.

When the Second World War broke out, Monnet put his contacts and belief in international cooperation to good use. He was sent to London to oversee British and French arms production. From

there he went to the United States, where he coordinated arms and aircraft purchases and encouraged American manufacturers to boost their output. Monnet met his "intimate friend" John Foster Dulles whenever he could. The two men shared a common vision for postwar Europe, one now being articulated by decision makers from Basel to Berlin and Washington, DC. There could be no return to the prewar system of nation-states, Dulles wrote in 1941:

> *We should seek the political reorganization of continental Europe as a federated commonwealth. There must be a large measure of local self-government along ethnic lines. This can be assured through federal principles, which in this respect are very flexible. But the reestablishment of some twenty-five wholly independent sovereign states in Europe would be political folly.*[16]

National sovereignty led inevitably to war, Dulles argued in 1942. "The fact of the matter is that economic unity in Europe has primarily been held back by a small group of self-seeking politicians in every nation. . . . Because a lot of politicians want to hold on to the trappings of sovereignty, are we to allow a condition to persist which makes recurrent war inevitable and which now, apparently, also inevitably involves our being drawn into such wars?"[17] Dulles's arguments for a federal Europe were rooted not in hazy idealism about a Europe living in peace and security for its own sake, but hard-headed realism: the preservation of American military and geopolitical interests, building a bulwark against the Soviets, and the preservation of the links between the prewar transnational financial elites in Wall Street and Germany. A united Europe was simply the best means to achieve these ends.

MONNET RETURNED TO Paris after the war's end and began to plan the supranational project that he had drawn up with John Foster Dulles. The ECSC was the first step on the road to today's European Union. The European federal project, like its financial agent the BIS, operated by stealth. The stated reason for the creation of the ECSC was to harmonize coal and steel production and sales in postwar Europe and usher a new spirit of economic cooperation and harmony between Germany and its neighbors that would prevent future wars. The real reason was to ensure the continuing dominance of the German steel and cartels and the power of men such as Alfried Krupp, whose industrial empire had worked eighty thousand slave laborers to death, and who was about to be released from prison by Monnet's close friend John McCloy.

The coal and steel barons intimidated even Ludwig Erhard, the architect of the German economic miracle, recalled Dutch politician Jelle Zijlstra, who had briefly served as prime minister from 1966 to 1967, before being appointed president and chairman of the board of the BIS, where he remained until 1981. Eight years after his retirement, as Europe prepared for the introduction of a single currency, Zijlstra gave a lengthy interview, where he spoke freely about the secret history of the European unity project.[18] The ECSC was a "political exercise" and fundamentally, was "an impossibility," Zijlstra said. The Germans "without any doubt" regarded it as a *dachorganisation* (umbrella organization) for their steel and coal cartels.

Zijlstra served as Dutch minister for economics for most of the 1950s. After a few months in office he went to visit one of Holland's largest coal and steel traders. His host warned him that the German coal and steel barons were so powerful that they were virtually a state within a state. Do not, he advised Zijlstra, upset them. Two months later, Zijlstra received an invitation to the Ruhr, Germany's industrial heartland, to meet the barons himself. He was wined and dined and received the same warning. Zijlstra,

then still in his mid-thirties, was not cowed. He thanked the coal and steel barons for their time and returned to Holland.

Zijlstra saw the ECSC for what it was: a cartel for the German steel and coal producers that fixed prices in their favor, while removing its members states' power to run two crucial strategic industries. He soon clashed with Ludwig Erhard. The German economist's commitment to free trade was less ardent when the country's own interests and those of the coal and steel barons were involved. Zijlstra berated Erhard and told him, "You are not true to your own faith." Erhard did not deny the accusation. He shrugged and told Zijlstra, *"Lieber Kollege, wir sind doch alle Sünder!"* (Dear Colleague, we are all sinners). "In that debate," recalled Zijlstra, "the coal and steel industrialists, the people from the Ruhr, saw the community as a possibility of extending their structures to the European system. And they were not, and they never have been free traders."

Back in 1944, as we have seen, McKittrick, the BIS president, was cutting deals with German industrialists with the support of the OSS and the State Department, as outlined in the Harvard Plan documents. The industrialists' postwar cooperation, McKittrick promised, would preserve their industries and even bring a guarantee of continued profits. The ECSC fit perfectly into that framework.

Zijlstra knew Monnet well. The French technocrat was an unelected bureaucrat, but he still had the power to instruct governments, including the West German government, said Zijlstra. If a problem arose, "Monnet went to see the governments and told them what they had to do. Monnet had an enormous authority over the national governments . . . he certainly visited from time to time the minister of foreign affairs and even prime ministers. He was very powerful."[19] Monnet's power had multiple roots. He was immensely charismatic and persuasive, with a sharp, precise intellect. But more than that, Monnet had John Foster Dulles, Allen Dulles, John McCloy, and the American government behind him.

Much of the United States political and intelligence establishment believed, like Jean Monnet, and indeed Winston Churchill, the wartime British prime minister, that a unified Europe would never go to war again, which meant that the United States would never have to go to war again in Europe. Germany needed to be locked into the unification project, both as a bulwark of stability, and as a counterpoint to rising Soviet power on the other side of the Iron Curtain. With Marshall Plan aid dependent on progress toward a federal Europe, the United States could, and did, wield enormous influence on the political structures of the postwar continent.

In May 1948, eight hundred delegates met at The Hague, under the chairmanship of Sir Winston Churchill, to create the European Movement, with the ultimate aim of a federal union. The movement's secretary-general was Joseph Retinger, a former adviser to the Polish government-in-exile during the war. At the same time, Allen Dulles and William Donovan were using their OSS contacts and expertise to set up the American Committee for a United Europe (ACUE). The ACUE's role was to channel funds to the European federalists and to use the new techniques of psychological warfare, such as the Harvard Plan, which had been honed during the war, to push for a united Europe.

Donovan was appointed chairman of the ACUE and Allen Dulles his deputy. Walter Bedell Smith, the director of the CIA, the successor to the OSS, also sat on the board. Between 1949 and 1960, the ACUE injected more than $3 million into the European Movement, always at least half of its budget and often more. As Professor Richard Aldrich, an intelligence historian, notes, the European Movement's officers and directors included at least four CIA officers. Donovan pushed hard for the creation of the ECSC. He gathered petitions from American and European politicians and released them to the press and directed a stream of federalist propaganda at members of Congress."[20] The message from Washington was consistent: Europe must unite. In April 1950, John McCloy gave a widely quoted speech in London, saying that the German problem could be solved only by a combination of economic and political factors,

echoing the arguments of Per Jacobssen in 1946. "The fact is, we cannot solve the German problem without fitting it into the larger context of a united Europe. . . . These economic factors lead directly to the political. To insure the freer flow of trade and the development of European markets will require effective political machinery." McCloy concluded, "I say no permanent solution of the German problem seems possible without an effective European union."[21]

From Paris to Washington, DC, the postwar committees and movements pushing for European federalism presented themselves as new and innovative, offering a fresh approach for a new era. But they were deeply rooted in the old ways of doing business—of powerful men gathering over lunch or dinner to reshape the world as they saw fit. During the war Allen Dulles had met with Thomas McKittrick and Per Jacobssen to plan the postwar European economic order. Jean Monnet had honed his thoughts on European unity with John Foster Dulles. Per Jacobssen had traveled to Berlin to share American plans for the postwar European economy with Emil Puhl, the BIS director, war criminal, and Reichsbank vice president. None of these discussions were made public, even though the plans hatched there would shape the modern world. The United States' involvement in the European project continued the tradition of secrecy and covert action well into the 1960s. A State Department memo, dated June 11, 1965, to Robert Marjolin, the French president of the European Economic Community, recommends that he pursue monetary union without public discussion. The memo advises him to suppress debate until the "adoption of such proposals would become virtually inescapable."[22]

THE NEW TRANSNATIONAL ECSC naturally needed a transnational bank. In 1954 the ECSC was negotiating with United States for $100 million loan. The monies were to be spent investing in coal and steel projects. The US government had pushed hard for the creation of the ECSC but was reluctant to lend it such a large sum. The ECSC was a new organization. Who knew if it would even exist in a few years? The BIS came to the rescue. The bank would act as the middleman between the ECSC and the United States and manage the loan. If the ECSC no longer existed when the $100 million was due to be repaid, the BIS would collect the money and would then repay the United States. The involvement of the BIS reassured the US Treasury. The loan was agreed. With the BIS's imprimatur the ECSC could now obtain credit on the international market.

The following year the BIS celebrated its twenty-fifth birthday. The bank's swift engineering of itself into the postwar global financial system was proving extremely profitable. Between 1950 and 1959 the bank's assets and liabilities increased 4.7 times, while gold deposits, mainly from central banks, increased by 14 times, and currency deposits increased more than fourfold. The bank was as discreet as ever. Compared to the complications of the war years, the new era of peace was far simpler to navigate. In 1955 the Bank deutscher Länder was prepared to lend $100 million to the Bank of France but feared domestic criticism during an election year. The BIS offered to hold the monies on deposit for the BdL while it was understood, although certainly not mentioned in the contract, that it would make an advance of the same sum to France. That France, a victor of the war, needed to borrow such a substantial sum from Germany, a defeated country, was testimony to the effectiveness of the Marshall Plan.

Newly confident of its future, the BIS had started to issue stern policy prescriptions to the world's governments. Jacobssen was still fulminating against the curse of rising prices. "The inflation mentality," demanded the 1956 annual report, "must be extirpated."[23] The BIS also criticized the cost of the substantial programs of public works launched by postwar European governments to raise standards of living, housing, and public services. "With regard to all these activities, the governments should, in the first place, abstain from inflationary methods of financing," warned Jacobssen in the 1956 annual report. "But usually that is not enough; if the private economy is to develop and maintain a high level of

investment for productive purposes—as would certainly be advantageous for a number of countries—other claims on resources must be kept within reasonable limits and in a great many cases this means that public expenditure should be curtailed."[24] An unelected, unaccountable, and secretive financial institution was issuing policy prescriptions for democratic governments.

This was Jacobssen's last report. He left the BIS in 1956 to run the IMF. Many of his colleagues were amazed at his decision. It was clear that the political dynamic was toward ever more financial and political European integration, all of which would need the BIS. And the project was working. Europe was stable and at peace. Trade and industrial production were breaking records. The BIS's future was assured. The European Payments Union, managed by the BIS, was so successful that by 1959 western European currencies became freely convertible into each other and into the US dollar.

The IMF was new and still defining its role. Sir Otto Niemeyer, the veteran British banker and former chairman of the BIS board, told Jacobssen that the IMF had no future and that he would be wasting his time there. But Jacobssen felt that after twenty-five years at BIS it was time to move on.

JACOBSSEN WAS NOT the only international banker on the move. In 1956 Eric Warburg joined Brinckmann, Wirtz & Company as a partner. Rudolf Brinckmann, the bank's owner and BIS director, ungraciously told Warburg that he should be grateful to be allowed to return to the successor bank to the House of Warburg. The dispute between the Warburgs and their former employee remained as rancorous as ever. Brinckmann still refused to change the bank's name back to Warburg, or even include the family name in the bank's title as it might mean a loss of Arab business.

Emil Puhl, the former vice president of the Reichsbank and BIS board member, also had travel plans. In 1954 Puhl applied for a US visa, despite his conviction for war crimes, which would under normal circumstances immediately disqualify such a request. But it seemed there were special rules for valued international bankers, even for Nazi financiers. Puhl gave the Chase National Bank, the employers of his old friend McKittrick, as his reference. During the trial of Walther Funk, Puhl's former boss, Thomas Dodd, an American war crimes prosecutor, told the court that Chase National had once offered Puhl a job in New York.[25] Perhaps the bank wanted to make this offer again. The US Consul General in Berlin wrote of Puhl's application, "It should be noted that the Consulate General has in the course of its examination found no other grounds that would prevent Mr. Puhl from receiving a non-immigrant visa. Mr. Puhl is one of the outstanding bankers in Germany and wishes to proceed to the United States on the invitation of several well-known American bankers to participate in discussions of some importance."[26] It is not publicly known if Puhl traveled to the United States, and if he did, with whom he met.

Donald MacLaren, the British spy who brought down IG Farben's American operation and who investigated IG Farben's postwar empire, returned home from Berlin to civilian life. MacLaren's analysis of IG Farben remains as incisive as ever. "It has been called a State within a State; in the end it almost became the State itself."[27] The defeat of Hitler was merely a temporary setback, MacLaren warned. His conclusions echoed the Red House Report on the Nazi industrialists' postwar plans and Puhl's conversations with McKittrick: "Men who built such an elaborate structure and who thought so thoroughly of every contingency in the past are not likely to disappear from the scene without leaving a group of younger men who wait for the day when our backs are turned and our interest wanes to gather again their scattered resources of money and men to engage once more in an attempt of economic domination of the world."[28]

MacLaren was correct. The key man was indeed younger, born nineteen years after Hermann Schmitz. A BIS veteran who had worked in Basel during the early 1930s, he would be fulsomely welcomed onto

the bank’s board.

"What a Blessing we have a Blessing."

— The American view of Karl Blessing, appointed the first president of the Bundesbank in 1958[1]

After fifteen years at the New York Federal Reserve, Charles Coombs was not easily awed. But even he was impressed at the financial firepower present at the BIS governors' meeting in December 1960. Gathered in one room, sipping their coffee in an anonymous former hotel near Basel railway station, were the governors of the banks of England, France, Germany, Italy, Sweden, Belgium, and the Netherlands. But despite their urbane appearance and easy familiarity with each other, the governors were worried men—as was Coombs himself.

The combined dollar holdings of their banks totaled $6 billion. Under the Bretton Woods system the dollar-to-gold exchange rate was fixed at $35 an ounce. As long as the London gold market stayed around that price, the value of their dollar reserves was stable. But earlier that year the price of gold had jumped to $40 an ounce. The dollar was a victim of its own success. There were too many dollars in circulation or held by national banks as part of their reserves to be redeemable for gold at $35 an ounce. Thus the dollar's value against gold was declining. The central bankers could sell their reserves, but such a move would certainly crash the dollar and fuel global instability.

The central bankers wanted to ask Coombs about the financial plans of the new Kennedy administration, which would take office in January 1961, he recalled in his memoirs.[2] Coombs's book provides a rare and fascinating glimpse into the secret deals reached at the Basel governors' meetings. The central bankers "were very worried men that day, genuinely distressed by the impending clash between their sworn duty to protect the value of their countries' international reserves and their fear of precipitating a dollar crisis by cashing in dollars for gold."[3] Much was riding on Coombs's answers. If he could reassure the other bankers, the dollar would retain their confidence. If not, he might trigger a worldwide financial crisis.

The bankers were reassured. The new US government would firmly maintain gold parity at $35 an ounce and would work to reduce the balance of payments deficit, Coombs promised. The governors welcomed his assurances and requested that he, or a representative of the Federal Reserve, attend every Basel meeting from now on, even if only as an observer. Thirty years after the founding of the BIS, the United States officially still kept itself at a distance. Three of the BIS's presidents had been American—Gates McGarrah, Leon Fraser, and Thomas McKittrick—but the Federal Reserve had never taken up the stock allocated to it at the bank's founding. Coombs was honored to be invited to the Sunday evening dinner, the "inner sanctum from which all lower ranking officials were normally excluded."

Coombs regularly attended the governors' meetings from 1960 until his retirement in 1975. He relished his time at the BIS. He usually left New York on Thursday afternoon, after the meeting of the directors of the New York Federal Reserve, and went straight to Idlewild Airport to fly to Zürich, arriving on Friday. From there he traveled to Basel and his usual room at the Schweizerhof Hotel, near the BIS. It was exhausting but exhilarating, with meetings and discussions on Friday night and all through the weekend until Monday morning when he flew back to New York. But his jet lag soon evaporated. "As the central bankers converged on Basel from all the European capitals and from Ottawa, New York, and

Tokyo, the fatigue of our journey seemed to vanish as we greeted old friends and listened to the inside story of what was really going on in the financial markets of the world."

Basel was the "ideal meeting place for central bankers seeking a refuge for quiet and confidential discussion of highly charged financial issues." In between the formal meetings, the bankers drifted down the corridors between their private offices, "always stopping to shake hands in the continental fashion with any colleague going in the opposite direction." The meetings were worth the trip in themselves, wrote Coombs, providing "not only a quiet testing ground for new ideas and approaches but also an early warning system when things were beginning to go wrong." The dinners, especially, gave "priceless access." "I could generally tell from those dinner discussions which birds would fly and which would not," he recalled.

Like couples who had been married for years, the bankers could read each other's minds. "There is something deeply satisfying in dealing with fellow professionals in any technical field. Never any speeches, everyone focusing clearly on the issue at hand, sentences frequently left unfinished because everyone instinctively knew the rest and in an almost uncanny way, a simultaneous realization of the appropriate technical solution. None of us were romantic internationalists, but where we could see a clear overlapping of national interests our minds instinctively reached out to one another in a true camaraderie of professional cooperation."

Coombs was especially impressed with Karl Blessing, the president of the Bundesbank, the new West German national bank, who "played a towering role":

> *As a young man he had worked on the staff of the BIS and once recounted to me his anguished memories of those days as he watched from Basel the breakdown of international financial cooperation in the early thirties. Now as President of the Bundesbank with the mark entrusted to his care, he wielded his enormous authority with courage and sensitive discernment of his world financial responsibilities. A cheerfully resolute man, Blessing was an unfailing source of strength and morale in all of our Basel meetings. I thought of him as truly a great man of his times.*

Blessing was indeed a man of his times, although not in the way that Coombs believed. The Bundesbank president embodied the new class of rulers in West Germany, many of whom were the same people who had managed Nazi Germany. Former Nazis ran or held senior positions in the banking and finance sectors, the military, the intelligence service, and government administration. Hans Globke, the national security adviser to Chancellor Konrad Adenauer, had helped write the Nuremberg anti-Jewish laws. Richard Gehlen, the head of West Germany's intelligence service, was the wartime chief of military intelligence on the Eastern Front, where the German army and SS troops had slaughtered hundreds of thousands of civilians. The directors of IG Farben, as we have seen, swiftly returned to lucrative business careers.

The unfortunate past of these men was rarely discussed. And Blessing, too, was adept at rewriting history, none more than his own. He had worked at the BIS during the 1930s, although his claim of "anguished memories" is risible. He had joined the BIS under instructions from his employers at the Reichsbank, with the express purpose of not facilitating, but wrecking international financial cooperation. Blessing's 1930 memorandum, "Opinion on How the Reichsbank Should Conduct Itself in the BIS," called for German officials to argue that reparations were "completely utopian," to make impossible demands, and to undermine the BIS's legitimacy in order to derail the Young Plan.

Blessing had returned to Germany in 1934 to work as an adviser at the Ministry of Economics. His patron, Hjalmar Schacht, then brought him back to the Reichsbank and appointed him its youngest director. Blessing loudly proclaimed his loyalty, declaring, "National Socialist economic and financial policy, like National Socialist policy for freedom and equality, has taken upon itself the law of action. We will allow no one in the future to strike this from our hand."[4] Blessing joined the Nazi party, and after the 1938 Anschluss—the absorption of Austria—he was rewarded with the job of absorbing the Austrian National Bank. It was joyous work for a true believer: "Just three months separate us from the memorable day, which will remain unforgettable for us. And yet in this short period, all the measures have been put into place with the goal of forging together the two economies into an unbreakable whole."[5]

Blessing was also forward thinking. When Germany's Jews were fined one million Reichmarks for the cost of the Kristallnacht pogrom in November 1938, he worried that Jews would sell their government bonds to raise the cash, which would drive down the market. The answer was for the Reichsbank to limit sales of Jewish-owned securities to one thousand Reichmarks.

The following year Blessing, together with Schacht, left the Reichsbank. Blessing had also signed the directors' memorandum criticizing Hitler's armaments spending. But the former BIS official was a canny survivor. He swiftly courted Walther Funk, Schacht's successor as president. With Funk's imprimatur, Blessing returned to the Reichsbank as a member of its advisory board. Blessing moved in the highest circles of the Third Reich. He attended thirty-eight meetings of the Himmlerkreis, the circle of Nazi industrialists who channeled funds to the SS chief through Special Account "S" at Kurt von Schröder's J. H. Stein bank. Blessing went on two trips with the group to visit concentration camps, guided by Himmler himself. Blessing later said of the Himmlerkreis, "I thought it was just for beer evenings."[6]

Blessing's importance went far beyond the monies he donated to the SS. He embodied the kind of intelligent, sophisticated technocrat who was essential both for the Nazi regime and for the perpetuation of German economic interests after the war ended. Hannah Arendt, the German-Jewish writer and philosopher, described the bureaucrats who organized the Holocaust as "desk-murderers." They did not raise a gun to the naked victims standing over the death-pit or pull the lever to release the gas. They merely stamped and moved pieces of paper from one government department to another and kept the money moving. But without them the Third Reich could not function. Blessing, too, was a desk-murderer.

In April 1939 Blessing joined the board of the German subsidiary of Unilever, a giant Anglo-Dutch company that manufactured fats and oils. The following year Germany invaded the Netherlands, and Blessing was appointed one of three administrators looking after Unilever's interests across the Reich. Meanwhile, Hermann Goering—the chief of the Luftwaffe, the German air force, and the minister in charge of the four-year plan—set up Kontinental-Öl to exploit the oil reserves of central Europe and the Balkans. This was a project after Blessing's own heart. He recognized the importance of Germany's allies in the east and south—Croatia, Hungary, Romania, and Bulgaria—as a means of ensuring Nazi economic hegemony and supplies of raw material. The Danube, he said, was the "river of the future," and petrol and grain would flow up it to Germany.[7]

Together with Walther Funk, the president of the Reichsbank, and Heinrich Bütefisch of IG Farben, Blessing was appointed to the board of Kontinental-Öl. As Christopher Simpson notes, the establishment of the Reich's oil company represented a triumph for the businessmen and bankers. The hardline Nazi ideologues around the SS wanted state control, government ownership, and centralized planning of the economy, especially of vital strategic industries. However the business elite, such as Schacht and Blessing, favored a more commercial approach.[8] Germany should dominate world markets, they believed, but there was no need to control every aspect of them. Kontinental-Öl was the answer: a government-supported monopoly to take over the oil industries of eastern Europe, with financial services provided by

Hermann Abs at Deutsche Bank.

Kontinental-Öl, like IG Farben, was built on plunder, exploitation, slavery, and murder. As the Nazi oil empire expanded eastward, Kontinental became one of the Third Reich's largest users of concentration camp inmates, ghetto workers, and prisoners. The firm ran at least ten concentration camps in Poland alone, where the workers were leased from the SS. In Ukraine, for example, Kontinental paid the SS and the German police administration five zlotys a day for a man, and four for a woman. The average life expectancy of a slave laborer was between three and six months. When Kontinental's camps were shut down, many of the inmates were shot. The Borisow camp was closed in March 1943 with about eight hundred prisoners still alive. According to Red Cross records, about eighty men and twenty women were evacuated to Smolensk, and the rest were executed.[9]

As the financial director of Kontinental-Öl, Blessing was at the epicenter of this nexus of death and profit. He oversaw its acquisition of new firms in the east. He managed the company "payroll," much of which was concerned with payments to the SS for the concentration camp labor the firm used—labor that was also used to build the new company headquarters in Berlin. Unfortunately for Blessing and his managers, the half-starved, traumatized labor force was not very productive. As late as March 1945, one of Blessing's underlings complained that work in Upper Silesia was being held up by the "use of concentration camp prisoners of low performance."

Blessing was arrested and imprisoned at the war's end, while the Allies considered whether to charge him with war crimes, as he certainly deserved. But behind the scenes, Blessing had powerful allies: Allen Dulles and Thomas McKittrick. The Nazi bankers and industrialists were correct in their belief that the western powers would need them to rebuild the German economy. In the contest between justice and realpolitik, Dulles would make sure that the latter would triumph.

In July 1945 the US occupation authorities asked Dulles to furnish a list of Germans "eligible on the basis of ability and political record for posts in a reconstituted German administration." The first set of lists was quickly submitted. But by autumn, Dulles, now running the OSS station in Berlin, had more detailed information about suitable German bankers. Much of this would have come from McKittrick.

In September 1945 Dulles submitted his new white list. It was divided into two categories: A and B. On the A list were three names judged suitable for "higher posts in a ministry." The B list contained five names that were suggested for "lesser posts such as Bureau head or division chief." [10] Among the names in group A was that of Ernst Hülse, the former head of the BIS banking department. Hülse, said Dulles, enjoyed "excellent connections with banking circles abroad," had a Jewish wife, and was definitely anti-Nazi. Hülse was appointed to the Reichsbank in the British zone and was named president of the central bank for the federal state of Nordheim-Westfalen.

The first name on the B list was that of Karl Blessing, whom Dulles described as a "prominent businessman and financial expert" with "considerable experience in international trade."[11] Dulles was well informed about Blessing's central role at Kontinental-Öl, which the American spymaster described as a "government-owned holding company organized to coordinate German-controlled oil properties throughout Europe." Dulles hedged his bets. Blessing's relationship with Kontinental-Öl might, he wrote, disqualify him for a "high government position." However Blessing had accepted the job "under pressure" and had been in touch with the German resistance. In addition, Dulles added, Blessing had not been a member of the Nazi Party. In fact Blessing had joined in 1937. And Blessing's party records were held by the US authorities, had Dulles bothered to check. Blessing's main claim to anti-Nazi activity was being included on the list of the July 1944 anti-Hitler plotters as a potential minister for economics. When the conspirators were arrested, Blessing was protected by Walther Funk, who told the Gestapo that Blessing had not known anything about the plot.

The whitewashing of Blessing was not the exception, but the rule. Declassified telegrams revealed that Dulles had long planned to rescue important German industrialists and scientists. In January 1945, Dulles wrote to William Casey, who was running operations inside Germany and who later served as CIA director in the 1980s:

> *My project contemplates that in normal course of events and without any prior contact with us but merely to escape impending chaos, important German industrialists, scientists, etc., will desire to find some haven, preferably Switzerland. If Switzerland is closed to them, these men might possibly turn to Russia as their only alternative. . . . Discreet preliminary conversations indicate some hope of securing Swiss cooperation."*[12]

Not everyone in Washington approved. The following month First Lady Eleanor Roosevelt wrote to her husband, "Memo for the President. Allen Dulles who is in charge of Bill Donovan's outfit in Paris has been counsel, closely tied up with the Schroeder Bank. That is likely to be the representative of the underground Nazi interests after the war. There seems to be in Paris a great many people who are pretty close to the big business side!"[13]

The president's wife was certainly well informed about the importance of the Schröder bank network, which reached from Germany to London and New York, and to the BIS via Kurt von Schröder. But by summer 1945, after the death of her husband, Mrs. Roosevelt's opinions counted for little in Washington.

Blessing was not charged with war crimes. Instead, with Allen Dulles's help, he was freed and returned to his old job at Unilever. He became one of the highest paid executives in Europe, earning $75,000 a year. Blessing took a pay cut to $50,000 a year when he joined the Bundesbank in 1958, but the power and prestige was ample compensation. By the early 1960s, when Blessing was a regular attender at the Basel governor meetings, he had transformed himself into a former member of the resistance.

Hermann Abs, of Deutsche Bank, was the most powerful commercial banker in the Third Reich, and he was not on Dulles's A list. Rather, he was high on an Allied blacklist of important Nazi officials to be arrested. In the American zone Colonel Bernard Bernstein, the head of the Finance division, had Abs, indeed all the Nazi financiers in his sights. Bernstein ordered that every banker and industrialist be detained as a suspected war criminal.

Luckily for Abs, he was living in the British zone. There he met his old friend, Charles Gunston of the Bank of England, whom he used to see in Basel during the 1930s at BIS meetings. Gunston was a senior official in the British occupation authority. Gunston had no interest in the Nazi atrocities. All he cared about was getting the banks working again. Gunston asked Abs to help rebuild the banking system in the British zone. Abs was more than happy to oblige. Bernstein was enraged and demanded that Abs be extradited to the American zone. Gunston refused, but in early January 1946 he returned to England. Abs was then finally arrested as a suspected war criminal, and he spent three months in prison before being released and was never charged. Instead Abs went to work, fulfilling his promise to his old friend Charles Gunston.

KARL BLESSING, LIKE Hermann Abs, certainly understood when to be helpful. In 1960 the gold spike threatened to undermine the stability of the postwar financial system. The United States and Britain proposed joint operations on the London market to protect the value of both countries' reserves. Blessing quickly offered to make some of West Germany's reserves available to the Bank of England. But any coordinated international action would need bilateral agreements, which would necessitate lengthy

negotiations with governments. Britain persuaded the United States that there was a much simpler approach to organizing multilateral interventions: through the governors' meetings at BIS. Between them the countries represented there, as well as the United States, accounted for about 80 percent of the world's reserves. The BIS staff was not enthusiastic about the idea. As the world pioneer in transnational finance, the BIS was a firm believer in the primacy of market forces. The market was now being shunted aside, wrote one official, "so that the inconvenience of certain financial policies can be avoided."[14]

Any such doubts were ignored by the governors. In November 1961 the London Gold Pool (LGP) was set up. The United States, West Germany, France, Italy, Britain, Belgium, the Netherlands, and Switzerland contributed a total of $270 million to the pool. The funds would be used to maintain dollar parity at $35 an ounce, in line with the Bretton Woods agreements. The banks would keep the gold price stable, by buying and selling when necessary. All of the participating banks agreed not to buy gold themselves on the London market while the pool was in existence. The BIS gold cartel was constructed on conditions of complete secrecy. There was not even a formal written agreement. The bankers' word, and a handshake, was enough to seal the deal. As Coombs noted of the governors' meetings, "However much money was involved, no agreements were ever signed nor memoranda of understanding ever initialized. The word of each official was sufficient, and there were never any disappointments."[15]

The Bank of England carried out the LGP's monetary transactions, but the BIS was essential to its operations. Every month the Bank of England reported to an experts' group of officials from BIS member banks and the BIS itself, which met at the BIS.

Eventually, word got out. The story was picked up by *The Times* (of London), then by *The Economist*. The LGP was forced to release detailed accounts, which were published in the Bank of England's quarterly bulletin. For the first five years, the LGP worked. The price in London stayed between $35.04 and $35.20 per ounce. The group of gold experts expanded their briefs to cover the foreign exchange market. The gold pool became the Committee on Gold and Foreign Exchange. It still exists today and is known as the BIS Markets Committee. The committee's agenda and deliberations remain secret.

THERE WERE TIMES, especially during crises, that the mutual trust engendered over the lunches and dinners in Basel proved crucial in stabilizing the global financial system.

November 23, 1963, was such a day. The assassination of President John F. Kennedy triggered panic selling on the stock market. Coombs was at work at the New York Fed when the news came through. He put aside his shock and horror and focused on the task at hand: the immediate defense of the dollar. Coombs considered banning foreign exchange transactions to prevent panic selling, but such a decision would be slow to implement and would need political support. Immediate action was needed, though, and he decided that closing the foreign exchange market was anyway not feasible. It would send a signal of panic and desperation. There would be a frenzy of selling of both dollars and gold.

The answer, Coombs decided, was for the United States to sell massive amounts of foreign currency to defend the dollar. The question was where could Coombs get it? He had access to only $16 million worth and held none at all of several major European currencies. He could sell gold to cover the purchases. But once news got out that the United States was selling its gold reserves after its president had been assassinated, the dollar would immediately plunge.

The best option was to borrow and sell foreign currency by drawing on the Federal Reserve's currency swap network. Currency swaps allowed Central Bank A to hold reserves in Central Bank B's currency (or a third currency), which Central Bank A could draw on, without having to purchase the foreign currency from Central Bank B. This was an excellent solution apart from one small problem: the time difference. No bank could draw on currency swaps without the approval of the partner bank. The

president had been shot at 1:30 p.m. Eastern Standard Time, six hours behind Europe. The European governors that Coombs urgently needed to contact had left their offices and were on their way to dinner or home. There were no mobile telephones or Internet. The governors were unreachable.

Coombs now faced the most important decision—or rather, gamble—of his life. If he bet wrong, not just his career would end. He would be remembered as the man who wrecked the dollar at a time of a national crisis. There was no time to consult or get the support of his superiors. A run on the dollar could start at any moment. Could he count on the governors of Europe's central banks to underwrite the sale by the Federal Reserve of hundreds of millions of dollars' worth of their currencies without their prior consent or knowledge? For if the sales went ahead, and the governors protested, or refused to authorize the transactions, both he, and the dollar, would be finished. The governors, he decided, would back him.

At 2 p.m., Coombs instructed the foreign exchange desk to offer 10 million deutschmarks for sale and to inform the bank acting as the Fed's agent that more such offerings would follow. Eight minutes later the Fed offered substantial amounts of sterling, followed by large holding of Dutch guilders and Swiss francs. Meanwhile, the Bank of Canada had stabilized the US-Canadian dollar exchange rate, and the Fed reciprocated.

At 2:30 p.m. Coombs ordered his officials to inform the market that the Federal Reserve would supply foreign exchange in unlimited amounts to defend the dollar and would call in its entire $2 billion of available credit swaps if necessary. Only then did Coombs report to Alfred Hayes, the president of the New York Fed. Meanwhile, the New York Fed's telephone operators were searching for the other central bankers. They reached Roy Bridge, of the Bank of England, first. He immediately agreed to help. Bridge told Coombs he could ask for "all that he wanted." The Bundesbank was equally cooperative. As soon as the Frankfurt foreign exchange market opened on the following Monday, the Bundesbank made sure to show itself as a buyer of dollars. In Bern the Swiss bankers agreed to enlarge the Fed's credit facility by another $100 million. Coombs's strategy worked. The stock market recovered. When the markets opened on Monday, the dollar remained stable.

THE BIS WAS going from strength to strength. In 1961 the ten key industrial IMF member states, known as the G10 (which largely overlapped with the membership of the BIS) set up the General Agreement to Borrow (GAB). The G10, plus Switzerland (which did not join the IMF until 1992) put aside $6 billion as a stand-by credit for the IMF. The GAB funds were to be made available if an IMF member was suddenly threatened by short-term capital flight. Two years later, the IMF began a detailed study of the international monetary system. It asked the BIS to provide information on the gold and Eurocurrency markets and central banks' short-term credit arrangements.[16] When the IMF report was published in 1964 it recommended that all G10 central banks send the BIS confidential statistics about their monetary reserves. The BIS, as the depository of this data, could then act as an early warning system if a country's reserves were being depleted and might need to draw on the GAB. So it seemed only natural that the Sunday evening governors' dinners at the BIS should be expanded to include Canada and Japan. (The two countries were members of the GAB but did not join the BIS until 1970.) The BIS had effectively relocated one of the most important international meetings of the key IMF members from Washington to Basel.

When in 1964 the central bankers of the European Economic Community set up their Governors' Committee to coordinate monetary policy, the committee was located not in Brussels, the home of the European project, or Frankfurt, the site of the Bundesbank, but at the BIS headquarters. The BIS helpfully provided the Governors' Committee with the necessary secretarial and administrative support. The following year, in 1965, the BIS even reached agreement on its 1930s investments in Germany—the

Young Plan loans. The Reichsbank had serviced the loans and paid interest until the end of the war in April 1945. After a twenty-year break, Germany agreed to resume paying interest on the loans but deferred the capital repayment until 1996.

The deal was brokered by Hermann Abs, who had returned to Deutsche Bank. Like Karl Blessing, Abs had expertly whitewashed his Nazi past. There was no mention of Abs's role at the bank that organized the plunder of Nazi-occupied countries, or his former position on the board of IG Farben. Abs had been the most powerful commercial banker in the Third Reich and now enjoyed similar status and acclaim in the new West Germany. He was also a welcome guest in the world's treasuries and chancelleries. Abs sat on the board of so many companies, including Daimler Benz, the Federal Railways, and Lufthansa, that a law, known as "Lex Abs," was passed limiting the number of positions an individual could hold to ten.

When Per Jacobssen died in 1963 after just seven years at the IMF, Abs became a founding sponsor of the Per Jacobssen Foundation. The list of his cosponsors reads like a roll call of the transnational financial elite and includes some familiar names, such as Eugene Black, the former president of the World Bank; Marcus Wallenberg, tutor to Thomas McKittrick and vice chairman of Enskilda Bank; Roger Auboin, the former general manager of the BIS; Rudolf Brinckmann, the veteran BIS director; Jean Monnet, the architect of European unity; and Marius Holthrop, the BIS president. Abs died in 1994 at the age of ninety-two, garlanded with honors and acclaim. A gushing obituary in the *Independent* newspaper, a normally skeptical British publication, acclaimed him as the "outstanding German banker" of his time. Which was true enough, as Abs had embodied a century of German banking, although not in the adulatory sense that the writer had envisaged.[17]

ALWAYS QUICK TO adapt to changing circumstances, the BIS spotted a new opportunity during the 1960s. The continuing drain on Britain's economy of its empire and the country's general economic malaise made sterling increasingly vulnerable. But sterling was also a reserve currency, especially across Britain's current and former dominions. Thus sterling, like the price of gold, had to be stabilized. The BIS was not a lender of last resort, but it could arrange loans to troubled central banks. In June 1966 a group of European central banks, the New York Federal Reserve, and the BIS agreed to make around $1 billion available to the Bank of England to defend sterling. This was significant, not just because of the sums involved, but because the BIS was its center. All the monies involved, apart from French and American funds, would be paid through a single account at the BIS. The bank was now coordinating a long-term strategic rescue of one of the world's reserve currencies.

However opaque the governors' meetings were, they were a more edifying spectacle than the farcical and very public scenes at the November 1968 G10 conference in Bonn. With the franc and sterling under pressure, and German reserves up by $4 billion, the conference was always going to be difficult.

This time the finance ministers were in charge. The bankers were banished to the lounges and corridors. Paris and London pressed for a devaluation of the mark, but Germany resisted. Roy Jenkins, the British finance minister, mentioned that the governors' meeting at Basel had favored revaluation of the mark. Karl Schiller, the German economics minister, rounded on Karl Blessing, the president of the Bundesbank. He demanded to know on what authority Blessing had discussed the national currency value with foreign officials, as though unaware that such discussions had been taking place at Basel since the BIS was established in 1930, and indeed were one of the main reasons for its existence. Schiller demanded that Jelle Zijlstra, the BIS president, provide him with a full report on the Basel governors' meeting. Zijlstra politely told him to "go to hell."

Excluded from the discussions, the governors spent their time playing Ping-Pong, drinking champagne

and hunting down an ever-shrinking supply of canapés, all of which were encased in aspic. At one stage Charles Coombs and the governor of the Bank of France eyed a single frankfurter on a waiter's tray. They agreed to divide it. Outside the conference center, hordes of television crews and reporters were besieging the building, while German protestors angrily demanded that those inside "save the mark." In fact, it was the French franc that needed to be saved, and the general consensus was that the currency would need to be devalued by around 11 percent.

Zijlstra went into action. He convened an emergency governors' meeting over lunch on Friday to see what support could be raised for the franc. It was an impressive performance. Zijlstra secured a pledge of $2 billion within half an hour. In the event, Charles de Gaulle, the president of France, decided that the franc would not be devalued. He introduced stringent exchange controls and other monetary restrictions. They worked until spring 1969, when French reserves began to drain away once more. Fresh attacks followed. The franc was finally devalued in August 1969, by 11.1 percent, just as had been discussed in Bonn.

IN DECEMBER 1969, Karl Blessing retired. His friends and admirers held a gala dinner in his honor. Blessing told those assembled—many of whom, like him, had airbrushed their past of inconvenient episodes—that "monetary discipline" had always been the center-point of his banking career. The Nazi regime, which he had loyally and enthusiastically served for all of its twelve years of existence, was smoothly dismissed. "We lived until 1945, or, rather, until 1948, with this many-headed, never-loved monster of the Reichsmark, going downhill all the time."[18] Blessing planned, he said, to spend much of his retirement in the south of France.

The following year, in 1970, McKittrick passed away at a nursing home in New Jersey at the age of eighty-one. The *New York Times* ran a glowing story about the "world financier," as it described him. McKittrick had stayed at the Chase National Bank until he retired in 1954. He later headed a World Bank mission to India. The former BIS president had been decorated by Belgium, Italy, and Romania, the article noted. McKittrick's secret deals with Nazi industrialists, his friendship with Emil Puhl and the BIS's acceptance of looted Nazi gold were not mentioned.

Montagu Norman had died in 1950, but Hjalmar Schacht continued roaming the world. Asian and Arab countries had no interest in his tainted history and welcomed his expertise. But others remembered. Around 1960 Schacht met with Sigmund Warburg because Schacht wanted Warburg to take a stake in a banking operation in the Philippines. The encounter was heavy with things unsaid. Schacht was unusually nervous, and his speech was repeatedly punctuated with the phrase "in short." Warburg listened politely and promised to think over Schacht's idea, but he never followed up.[19] Schacht finally retired in 1963 and lived in Munich with his second wife, Manci. He died in 1970 after he slipped and badly hurt himself while trying to put on his formal dinner trousers.

Blessing's retirement was short. In April 1971, at the age of seventy-one, he suffered a heart attack while on holiday in Orange, in France. Even in death, the myths and lies endured. The *New York Times* marked Blessing's passing with an article as laudatory as its summary of McKittrick's career. After Blessing left Unilever, the Times noted, he had "held various less exposed positions in the mineral oil industry."[20] As for the slave laborers, leased for a few zlotys a day from the SS before being worked to death or executed at Kontinental-Öl's network of concentration camps, it was as if they had never existed.

"To be frank, I have no use for politicians. They lack the judgment of central bankers."

— Fritz Leutwiler, BIS president and chairman of the board, 1982–1984[1]

By 1970 Rudolf Brinckmann had served on the BIS board for almost two decades. But his membership in the world's most exclusive club had not made the German banker any more amenable to settling the bitter dispute with the Warburgs over the name and ownership of the bank they both claimed. Eric Warburg, now seventy years old, remained a partner in Brinckmann, Wirtz & Co. He still went to work each morning to the building, which had once belonged to his family and which he felt was rightly theirs. Warburg and Brinckmann both attended the bank's morning meeting, then ignored each other for the rest of the day. The whole situation, Warburg said, was "unbearable."

The Warburgs suggested that the bank be renamed M. M. Warburg, Brinckmann & Co. The BIS director offered Brinckman, Wirtz–M. M. Warburg & Co., and so it went on. But Brinckmann could feel that Germany's bankers were turning against him. Hermann Abs described the imbroglio as a scandal. But it may have been Jacob Wallenberg, of the Swedish banking dynasty, who finally forced Brinckmann to change his mind. On a visit to the bank's Hamburg headquarters, Wallenberg told Brinckmann that when he had first come to the building, in 1913, the name of the firm was "M. M. Warburg & Co, and not, as today, Brinckmann, Wirtz & Co."

Brinckmann finally surrendered in 1969, and the bank was renamed M. M. Warburg–Brinckmann, Wirtz & Co. The following year, he stepped down from the board of the BIS. Brinckmann retired from his, that is, the Warburgs', newly renamed bank on the last day of December 1973, at the age of eighty-four. Their battle won, the Warburgs proposed that the bank hold a farewell reception for Brinckmann at the Hamburg branch of the Bundesbank. The gala event was planned for January 2 the following year. The two sides planned a gracious closure, both of Brinckmann's career and of a long and often turbulent relationship that had spanned five decades. But it was not to be. As Eric Warburg and Rudolf Brinckmann walked toward the Bundesbank building, Brinckmann suddenly gasped for air, collapsed, and died.[2]

THE PASSING OF Brinckmann, like that of Hjalmar Schacht and Karl Blessing, marked the end of the postwar era, the transition to the modern, globalized, economy and the rise of the new generation of central bankers. Money moved faster, markets reacted quicker, and countries were now interconnected in ways that would have seemed inconceivable when the BIS was founded in 1930. Its headquarters, at the former Grand Hôtel et Savoy Hôtel Univers, at Centralbahnstrasse 7, had served the central bankers well for several decades. But it had been built as a hotel, not as the headquarters of an international bank that was rapidly growing in power and influence and which stood at the heart of the European integration project. In 1958 the BIS employed 158 staff. By 1971 that number had grown to 237. The bank's membership was steadily expanding, as was the bank's growing global reach. The national banks of Spain, Portugal, Iceland, South Africa, Turkey, Canada, Australia, and Japan had all joined. BIS membership was now a point of pride for the newly emerging economies. The monthly governors' meetings needed to cater not just to the central bankers, but to the legions of assistants, staff, and junior officials who invariably accompanied the governors.

Richard Hall returned to the BIS in 1972, rising to become assistant general manager (the equivalent of deputy manager) before his retirement in 1992. Hall had first spent eighteen months at the bank in 1955 and 1956, seconded from the Bank of England to work on the European Payments Union. That era now seemed something from the pages of a dusty history book. "Things like exchange controls and the gold standard had occupied a lot of people's time then. But the world had changed tremendously between 1956 and 1972, and the BIS had changed with it," he recalled. The BIS had survived, evolved, and was now certain of its place in the world. "The bank felt more confident. Not only had it survived the immediate postwar problems, but it had gone on to demonstrate its usefulness to central bank governors as a place for coordinating, consultation, and even weeping on each other's shoulders sometimes about how dreadful these governments are. The central bankers would share their worries and responsibilities and someone else would say, 'Yes, I have one of those as well, do you have any good ideas for dealing with this?'"[3]

The BIS commissioned Martin Burckhardt, a local architect, to design a new, custom-built headquarters. Burckhardt drew up a plan for an ultramodern circular tower block with twenty-four floors. The first version was rejected as too high. Even after the tower was shortened, some local residents objected. A city-wide referendum was held, and the building's supporters won an overwhelming majority —32,000 in favor, while 14,000 voted against.[4] The foundation stone was laid in 1973, and the bank moved into its new offices in 1977. The move was essential, said Richard Hall. "Some of the staff had regrets, but others thought it was about time. The old building had its limitations, and we had burst out of it. We needed more space for more people."

For a staid and secretive organization, the BIS had chosen a surprisingly high-profile headquarters. Where once the entrance to the BIS had been tucked away next to a chocolate shop, the new building, at Centralbahnplatz 2, was eighteen stories high. It loomed almost menacingly over downtown Basel, like a rocket about to take off and launch itself into space. The sunlight glinted off the rows of opaque, bronze-tinted windows. The national flags of member banks stood in a row by the entrance, like a miniature United Nations. The bank's circular corridors and globular 1970s furniture were very stylish, if not daring, for staid central bankers. Even now, the building, which is still in use, appears to have been transplanted from a 1970s James Bond film, as though a steely eyed villain might suddenly stride down its long, looping corridors and frog-march an unwary visitor into a secret annex.

The veterans of the bank grumbled about the "Tower of Basel" as it soon became known. The BIS was no longer invisible. Tourists gawped, and locals took pride that the world's most influential bank was now on display for all to see. Fritz Leutwiler, the president of the Swiss National Bank as well as the BIS, did not approve at all. In the old building, Leutwiler knew when the governor of the Bank of England was in the neighboring office, because he could hear him walking down the corridors and opening his door. The building's prominence infuriated Leutwiler, who like many bankers of his generation believed that the BIS's affairs were best conducted with as low a profile as possible. "That was the last thing we wanted. If it was up to me, it would never have been built," he said of the new headquarters.[5]

The new headquarters were not just stylish, but enjoyed state-of-the-art technology. The BIS managers had realized early on the importance of computers for international finance. They understood that the rapidly globalizing economy would demand ever faster and more secure means of transmitting and storing data. The bank would play a central role in collating, analyzing, and cross-border banking transactions. It provided the secretariat for the G10's group of computer experts who were developing electronic systems for messaging and automated international payments. The BIS also operated an experimental data bank, which provided macroeconomic data for central banks. All this demanded high levels of security. The BIS's safety and security features are now standard on government and corporate headquarters, but in 1977 they were ahead of their time. The bank, still protected by international treaty, guards its sovereignty

as keenly as its secrecy. Thus the architects, and the bankers, tried to plan for every conceivable eventuality. That meant making the building as self-contained as possible. The Swiss authorities need the permission of the management to enter the premises. By far the best thing was to ensure that there would never be a reason to summon them.

The Tower of Basel boasts its own bomb shelter in the basement, a sprinkler system with two backup levels, in-house medical facilities, and lengthy underground corridors to house its archive. Most visitors —apart from central bankers—may not walk anywhere unattended and must call for an escort to walk from room to room. They are not allowed into the staff canteen, which serves lunch every day from 12:30 to 2 p.m, and they must leave the bank at this time. The security guards, who keep a close watch on the building through an extensive CCTV system, will quickly terminate any unauthorized wanderings, and the errant stroller will likely be escorted from the premises. The top floor, which hosts a superb restaurant, is certainly out of bounds, for that is where the governors gather for dinner on Sunday evenings. The aim, said Gunther Schleminger, the bank's general manager under President Leutwiler, was to provide "a complete clubhouse for central bankers." The BIS staff also have their own luxurious country club just outside Basel, with tennis courts and a swimming pool.

It takes a certain verve to build an eighteen-story circular block in the middle of one of Switzerland's most important and historic cities, especially when the organization housed inside is not subject to Swiss jurisdiction. But the BIS has always been a survivor, swiftly adapting to changing circumstances and decisively building itself into the evolving global economy. The new headquarters was a statement—in concrete and tinted glass—that, at the age of thirty-seven, the BIS had come of age. The Tower of Basel, like the bank itself, was nearly invulnerable. Naturally, the high-profile building did not bring any relaxation of the bank's obsessive secrecy. Passers-by could stare at the building but still had no idea what went on inside. The details of the BIS's transactions for the central banks, the deliberations of the governors' meetings, and the bank's powerful committees remained confidential.

The rapidly globalizing economy, argued the governors, made that confidentiality and trust between the central bankers and the BIS even more crucial. During the Second World War, the BIS had acted as an information channel between the Allies and the Axis. It served the same purpose during the Cold War, as a neutral and extremely comfortable meeting point for the Communist and capitalist worlds. Central bankers from behind the Iron Curtain regularly visited the BIS, not just to obtain credit, but also to draw on the bank's expertise in the gold and foreign exchange markets. The BIS was always generous to its visitors from behind the Iron Curtain. It covered their travel costs and paid them a per diem in hard currency. Once in Basel, plied with fine food and wine, with some Swiss francs in their pockets, the Eastern Bloc bankers were friendly, loquacious, and a most useful source of economic intelligence.

This worked so well that by 1976 the central bankers of the Eastern Bloc countries even had their own biannual governors' meetings at Basel, hosted by the BIS. The more the Communists adapted to capitalism, the sooner their system would collapse, the BIS managers believed—correctly as it turned out. Senior BIS officials also regularly visited East European capitals to meet with central bankers. Budapest, where life was much more pleasant than in Warsaw or Bucharest was a favorite. Hungary was often at the center of the BIS's Cold War intrigue. As the BIS annual report for 1982–1983 primly notes, the BIS and the National Bank of Hungary had a "long-standing business relationship."

The central European nation was one of the BIS's earliest members. One of the bank's first acts was to extend credit to Hungary and several of its neighbors, in 1931. The relationship had endured through the Cold War and by the early 1980s was about to flower. János Kádár, the Hungarian leader, was tentatively experimenting with limited private enterprise. Kádár's "Goulash Communism," as it was dubbed, was being watched with great interest in the West. Hungary's economy was the most liberal in

the region, and the country applied to join the IMF in 1980. Frigyes Hárshegyi, a veteran Hungarian banker, first visited the BIS in 1978. Hárshegyi was then the Hungarian delegate to the International Investment Bank in Moscow, which served the Soviet Union and its socialist allies. At this time Western commercial banks were lending to the socialist countries, but capitalist banking mechanisms demanded a steep learning curve from the East European financiers who were used to operating in a state-controlled economy. The meetings at Basel helped Hárshegyi and his colleagues to understand how a free market banking system worked, he recalled. "The BIS was like a stock exchange of information. The atmosphere was always friendly, avoiding political statements and concentrating on financial and professional questions."[6]

But Hungary had a problem. Foreign borrowing had financed Goulash Communism, which had brought social peace by providing work, housing, holidays, and limited travel to the West. By 1982 Hungary owed more than $10 billion in foreign debt, much of it short-term.[7] The imposition of martial law in Poland and the subsequent debt crisis together with the parlous state of the neighboring Romanian economy had alarmed investors and the international markets. Even though Hungary was in a completely different situation, with a far more liberal regime and some promising economic indicators, the "regionalization" factor meant that Hungary's creditors were rushing for the exit. Money was flooding out.

János Fekete, a senior official of the Hungarian National Bank, was charged with persuading the BIS to help. He had excellent contacts at the BIS and regularly attended meetings there. Fekete was optimistic that Hungary would be allowed to join the IMF, and indeed the country would not have applied without positive signals from the fund's Washington headquarters. IMF membership would anchor Hungary firmly in the global financial system, instead of the Soviet make-believe equivalent. But the fund moved slowly, and Hungary's creditors were pressing hard. The legendary ingenuity of Hungarians was being tested to the limit. The Hungarians have brought the world numerous inventions, from the ballpoint pen to nuclear weapons. Indeed they are famed for being so wily that the old joke defines a Magyar as "someone who enters a revolving door behind you but comes out in front." Fekete proved similarly inventive.

Hungary desperately needed funds, Fekete explained to Fritz Leutwiler, but lacked sufficient foreign exchange or gold reserves. The Hungarian banker suggested that the BIS organize a bridging loan, until Hungary could join the IMF and apply for financial assistance. The BIS loan would be returned as soon as Hungary was in the IMF and received its first credit. Leutwiler was minded to look sympathetically on Fekete's request. Leutwiler understood that the regionalization approach, which equated comparatively liberal and forward-looking Hungary with totalitarian Romania or Poland, languishing under the rule of the generals, showed poor judgment. Hungary, and Fekete, were old friends of the BIS. The BIS was always very helpful, says Hárshegyi, Fekete's former colleague. "They saw that this was a short-term crisis and that Hungary's economic philosophy was always to service its debts."[8]

Once again, the personal connection proved crucial. Leutwiler called Jacques de la Rosière, the managing director of the IMF, in Washington. The BIS president wanted to know two things. How was Hungary's membership application progressing? And would Budapest be likely to receive IMF assistance?

With hindsight, a lot was riding on this telephone call, probably more than either Fekete or Leutwiler realized. Had de la Rosière signaled that Hungary's IMF membership application was not likely to be approved, or even just that it was stalling, Leutwiler would likely have politely ushered Fekete from his office with no firm commitment to help. The capital exodus from Budapest would have continued, the economy would have faced collapse, and the country's tentative experiments with the free market would doubtless have ended. The reformers within the Hungarian politburo would have been weakened and the hard-liners, who opposed what they saw as dangerous capitalist experiments, been greatly strengthened.

Such a course of events would certainly have been "regionalized." The defeat of the Hungarian liberals would likely have been mirrored across the Soviet bloc, perhaps even in Moscow, where Hungary was regarded as a licensed wild card, able to test the capitalist waters in ways the Soviet Union could not. De la Larosière was able to reassure Leutwiler: Hungary would soon be a member and qualify for financial assistance. Thus reassured, Leutwiler agreed to Fekete's request for a bridging loan. In March and May 1982 the BIS arranged two loans to Hungary for a total of $210 million, and a further $300 million followed in September. By the end of the year, Hungary had joined the IMF. The fund's board approved a credit line of $520 million. Hungary repaid its debt to BIS.

Unbeknown to him, Leutwiler had set in motion a series of events that would soon help to redraw the map of Europe. The backing of the BIS and the IMF sent a powerful signal that the Fund, and the BIS and its shareholders—other central banks—had faith in the Hungarian leadership's plans for reform. The Hungarian reformers further liberalized the country's economy. Private entrepreneurs began to push the limits of freedom, and foreign investors looked at Hungary with renewed interest. Hungary's international bankers, like Hárshegyi and Fekete, already saw the deficits of the socialist system. Their visits to Basel only reinforced their understanding of its profound inefficiencies and stultifying effect on business. The central banks in the socialist bloc had very different functions to their capitalist counterparts. The Hungarian National Bank was a state commercial bank, supplying credit and financing foreign trade. The Basel meetings were also valuable tutorials in how to turn a socialist state bank into a traditional central bank, responsible for controlling the money supply and controlling interest rates.

By the late 1980s, even the old guard realized that the one-party state did not work. The Hungarian leader Kádár resigned, and negotiations began for a peaceful transition to democracy. The Iron Curtain was first opened in Hungary, three months before the Berlin Wall was breached. One day in August 1989 tens of thousands of East German refugees gathered on the Hungarian-Austrian frontier. By then it was clear that Communism was dying. As they surged forward, the border guards stood by and let them through. By the end of the year the entire Soviet bloc had collapsed. The BIS had played an important role in this process. The bank's bridging loan had reinforced international confidence in the Hungarian reformers, which in turn had boosted their political standing at home, which had weakened the grip of the Communist party and allowed the opening of the Iron Curtain. That in turn triggered a domino effect across the region and accelerated the collapse of the one-party system.

The Soviet Union itself was less welcome in Basel. Part of the problem was that Moscow still claimed ownership of the gold holdings of the Baltic States—Latvia, Lithuania and Estonia—which Thomas McKittrick had refused to hand to the Soviets back in 1940. By 1980 the three states no longer existed and had been absorbed into the Soviet Union. But the gold did exist, and the Russians wanted it. The Soviet Union continued to inquire about membership possibilities during the 1960s, but the bank remained steadfast. The BIS continued, correctly, to keep possession of the Baltic reserves—and was duly vindicated when the three Baltic States regained their independence in 1991 and the Soviet Union collapsed. The Bank of Russia was finally admitted in 1996.

Mexico too was on the brink of going bust in 1982—and taking the international banking system down with it. Mexico was saddled with an $80 billion external debt. In order to meet its obligations, Mexico had been borrowing overnight funds in New York to pay the interest. But the loans were eating themselves: each day Mexico had to borrow more to pay the interest on the previous day's loans. The Mexican economy was in danger of entering a death spiral. The IMF was prepared to loan Mexico $4.5 billion, but the fund moved slowly, and the paperwork might take months to be approved. Here, too, the BIS connection helped save the country. Paul Volcker, the chairman of the US Federal Reserve, and Fritz Leutwiler, the BIS president, organized a rescue package.[9]

Back in 1968 when Jelle Zijlstra, the BIS president, had sought to secure the French franc at the Bonn IMF conference, he managed to secure pledges of $2 billion over lunch. Volcker and Leutwiler took slightly longer, although their mission was slowed by the fact that the bankers were not gathered around a single table, as they had been in 1968. As with Hungary, the BIS financing was not intended as a substitute for the IMF rescue package but would be a temporary stopgap, until the IMF loans were authorized.

Volcker's initial suggestion of $1.5 billion was bumped up to $1.85 billion, with $925 million from the Federal Reserve, and the remainder to come from the central banks would be channeled through the BIS. Similar arrangements soon followed for Brazil, Argentina, and Yugoslavia. These arrangements suited everyone involved. The rescue packages were presented as BIS-led. The bank had arranged the loans, but the United States and the other G10 countries made the actual funds available. The rescue packages carried substantial political risks for the participating central banks, especially the Federal Reserve. But the central role of the BIS internationalized the bailout.

BY THE MID-1980S, the controversy over the Tower of Basel had faded away. The sleek, modernist building, looming over Centralbahnplatz, had become part of the Swiss city's urban skyline. The circular tower block, pointing skyward, symbolized the bank's new reach and ever more ambitious aspirations. The bank had shown a protean ability not just to survive but to flourish in rapidly changing circumstances. The ostensible reason for the BIS's foundation—the management of German reparations payments for the First World War—was now a fading memory. So was the Bretton Woods conference, where Henry Morgenthau and Harry Dexter White had tried to have the bank closed down. The financial system designed there, which fixed the price of gold at $35 an ounce was also gone, ended by President Nixon in 1971.

But the BIS now stood at the center of the global financial system. Leutwiler, the BIS president, had saved the Hungarian economy with a telephone call and accelerated the process of political reform that would eventually bring down Communism. The bank was managing multiple bailout packages that were easing the Latin American debt crisis and so preventing a potential catastrophic run on American banks. Some banks however, could not be rescued. There, too, the BIS positioned itself at the center of events. In 1974 the Franklin National Bank in New York and the Bankhaus Herstatt in Germany went bust after overextending themselves. At the time, Franklin was the biggest American bank in history to fail. Herstatt was a much smaller private bank but did substantial foreign exchange business in the United States. In response the BIS and the G10 governors set up the Basel Committee on Banking Supervision to begin the long, complicated, and still ongoing process of regulating commercial banks. The committee, naturally, was based at the BIS, from where it operates to this day. By hosting and providing secretarial and administrative services to new transnational financial groupings, such as the EEC Governors' Committee and the Basel Committee on Banking Supervision, the bank was steadily making itself indispensable for the functioning of the global economy. The committees' location in the Tower of Basel brought prestige, a stream of admiring visitors and dignitaries, and a new sense of permanence. There were no modern equivalents of Henry Morgenthau or Harry Dexter White, demanding that the BIS be closed down.

The BIS was also surprisingly nimble. The bank had been an early adopter of computer technology and its ultrasecure databases, which were hosted in the tower, were fast becoming the essential reference store for information on central banks and cross-border banking transactions. Some of that information was collated in the bank's annual reports that were ever more informative and had become required reading in the world's treasuries, finance ministries, and trading houses. The *58th Annual Report*, published in June 1988, was 223 pages long. Its eight lengthy, detailed sections included the bank's analyses of general economic developments, international trade and payments, domestic and international

financial markets, monetary policy, the international monetary system, and the BIS's own banking activities. These were increasingly lucrative. The accounts for the year ending March 31, 1988, showed a net tax-free profit of almost 96 million Swiss gold francs, an increase of almost five million more than the previous year.

Tucked away on pages 197 and 198, under the report of the bank's functions as agent, trustee, and depositary, and written in a banker's dry prose, were telling details that highlighted the BIS's central and vital role in the European integration project. Behind the scenes, the BIS continued to provide the financial expertise and technical assistance for the most significant economic development in postwar history: the drive toward European union. From the secret wartime discussions between Per Jacobssen, the bank's economic adviser, and Emil Puhl, the BIS director and Reichsbank vice president, to the detailed plans for the implementation of European Monetary Union in the late 1980s, the BIS played a driving role at every stage.

The BIS managed the 1947 Paris agreement on multilateral payments. Three years later the accord grew into the European Payments Union and the BIS was appointed the new system's agent. When European currencies became convertible, the EPU became the European Monetary Agreement that was managed, naturally, by the BIS. The BIS was deeply entwined with the European Coal and Steel Community, the first supranational European organization. It had signed an Act of Pledge with the ECSC in 1954 and subsequently handled all the loans issued by the ECSC. The BIS imprimatur gave the fledging organization vital credibility on international markets. The last ECSC loan had been redeemed in 1985–1986, and all unused funds had been returned to the European Commission in Luxembourg, the bank's 1988 annual report noted.

The BIS had hosted the Committee of Governors of European Economic Community Central Banks since it first met in 1964 and provided its secretariat. The EEC Governors' Committee coordinated and integrated the monetary policies of its members, a precursor to eventual European economic union. The committee was independent of the BIS, but its members later included Alexandre Lamfalussy, the bank's general manager from 1985 to 1993. The committee managed the first limits on exchange rate fluctuations within European currencies, a mechanism known as the "Snake in the Tunnel," which was an important step toward European monetary union.

The EEC Governors' Committee was significant, said Richard Hall, the former assistant general manager of the BIS. "The discussions in the European Economic Community were intergovernmental and central bankers were always number two to ministers. But the central bankers had been coming to Basel for many years, before monetary union was discussed. They were accustomed to talking together and doing things together and they did not want to be upstaged by finance ministers. They were already in Basel once a month for the BIS meetings, so they set up the committee there and the bank was very happy for them to do that."[10]

The BIS was the agent for the European Monetary Cooperation Fund, which had been set up by the Committee of Governors to manage short-term credit arrangements for members of the European Economic Community, the predecessor of the European Union. The bank was also the agent for the clearing and settlement system for the European Currency Unit (ECU) that was the precursor of the euro.

The establishment of the European Coal and Steel Community and its evolution into the European Economic Community were presented as an unmitigated boon for the countries concerned. But the most dramatic and far-reaching peaceful re-ordering of Europe in modern times—the steady and relentless erosion of national sovereignty—was implemented by sleight of hand. The key, for both the European project and the ever-broader mandate of the BIS, was to present decisions, policies, and actions as "technical" and "apolitical," of no concern to the average informed citizen. In fact, the opposite was true.

There could hardly be anything more political than the handing over of national powers to unelected supranational bodies, while the necessary financial mechanisms were arranged and managed by a secretive and completely unaccountable bank in Basel.

By the late 1980s this process was effectively unstoppable. In the summer of 1988 the EEC central bank governors were asked to serve, in their personal capacity (so that they would not be seen as representing their national banks), on the Committee for the Study of Economic and Monetary Union (EMU), which prepared for the adoption of a single European currency, the euro. The committee was better known by the name of its chairman, Jacques Delors, a French civil servant and politician.[11] Delors was president of the European Commission, which oversees the implementation of European laws and policies.

The Delors Committee had seventeen members, including Karl Otto Pöhl, the president of the Bundesbank; Robin Leigh-Pemberton, the governor of the Bank of England; and Willem Duisenberg, the president of the Netherland National Bank, all of whom were board members of the BIS. The questions of how, when, and even if EMU should be carried out were left to the politicians. The committee was concerned with the technical aspects, rather than the political implications. Once again, the BIS was at the center of events. The Delors Committee did not meet in Brussels, the site of the European Commission, or Strasbourg, the home of the European Parliament, or Frankfurt. It set up shop in Basel. There it enjoyed its own dedicated support staff, supplied by the BIS.

Behind the scenes, one of its most influential members was Alexandre Lamfalussy, the Hungarian-born BIS general manager. Lamfalussy had fled his homeland after the Soviet takeover in the late 1940s. He moved to Belgium and taught at the Catholic University of Louvain and later at Yale. Lamfalussy joined the BIS in 1976 as economic adviser, the post once held by Per Jacobssen. In 1985 he was appointed general manager. Lamfalussy was widely regarded as the intellectual powerhouse behind European economic integration and, from the project's earliest beginnings, had a deep grasp of both its practical operation and theoretical underpinning. When the Snake, the fixed-limit exchange rate mechanism, had run into trouble, for example, the governors had turned to Lamfalussy for advice.

So it was only natural that the Delors Committee would frequently defer to Lamfalussy's opinions, all of which greatly annoyed European officials visiting from Brussels. They could not understand why the great European monetary integration project was being directed from a suite of rooms in a tower block by Basel central railway station, which was out of their political and legal jurisdiction. But Delors's primary concern was not the prickly Eurocrats, but the central bankers. He understood that without them EMU could not take place. "It was the genius of Delors, who was a great manipulator—in the good sense of the term—who realized that he absolutely did not want to and would not hurt the feelings of the governors of the central bank," Lamfalussy recalled.[12] Logistics also played a role. Many of the Delors Committee's most important members, such as Pöhl and Leigh-Pemberton, already came to Basel for the governors' meetings. There, at the Sunday evening G10 governors' dinner, the central bankers decided what Lamfalussy described as the "norms of cooperation," in circumstances as secretive as ever. "This was the dinner where we talked about the most difficult issues, with no notes or anything."[13]

The Delors Committee also had two rapporteurs: Gunter Baer and Tomasso Padoa-Schioppa. Baer had worked as an economist at the BIS. Padoa-Schioppa was an Italian economist who is considered one of the intellectual founding fathers of the euro. The rapporteurs were immensely influential. They prepared the meetings, wrote reports, and "held the fountain pen," as Lamfalussy put it. "It was my officials that prepared the meetings in Basel of a project that was primarily European."[14]

The Delors Committee presented its report on EMU in April 1989. Central banks' reserves would be off limits to governments. Borrowing in non–European Community currencies should be limited. There

would be sanctions against countries that exceeded a budget deficit threshold (currently three percent). Crucially, the sanctions would apply not just to members of the future Eurozone, but to all European Union member states. The report called for European countries to take substantial steps toward economic convergence, budgetary discipline, and price stability, before moving decisively toward economic and monetary union.

However it was unclear how this strict, common financial discipline would be imposed. A common monetary policy, based on a shared currency, demanded a common fiscal policy with shared rules for government taxation and spending, Lamfalussy argued in a memo in January 1989, but there were no plans for this:

> *In short, it would seem to me very strange if we did not insist on the need to make appropriate arrangements that would allow the gradual emergence, and the full operation once the EMU is completed, of a Community-wide macroeconomic fiscal policy which would be the natural complement to the common monetary policy of the Community.*[15]

As Harold James notes, Lamfalussy's memo was both "apposite and intellectually compelling."[16] It neatly summarized the contradiction of a transnational currency with no transnational fiscal policy—a contradiction that remains unresolved and has both triggered and fueled the Eurozone crisis. The following month, Lamfalussy, during a discussion of the kind of controlling and supervisory budgetary methods needed for EMU, even suggested adding the word "enforceable" to the final draft. His suggestion was not incorporated into the report. Nonetheless, even without a common fiscal policy, Lamfalussy argued that Europe must press ahead with monetary union, if only because the European Monetary System (EMS), which limited exchange rate variations, had fallen victim to the law of unintended consequences. The system intended to stabilize currencies was having the opposite effect.

Speculators were pouring money into Italy. There inflation in 1988 was around five percent, compared to Germany at 1.3 percent. High inflation meant higher interest rates, but as the lira was locked into the EMS, its value was guaranteed. For investors there was no downside. The liberalization of capital movements had accelerated this process. The EMS was vulnerable, argued Lamfalussy and Europe must move to EMU as soon as possible. "It is for this reason that I would be in favor of a first stage that could be implemented as quickly as possible and not in a two or three year distant future, but starting this autumn or at least at the end of the year."[17]

The Delors Report, as it became known, was forty-three pages long. It was accompanied by a collection of fifteen papers which were written by the members of the committee. The influence of the BIS was clear. Jacques Delors wrote two of the papers, the first with the kind of grandiose title beloved of French politicians: "Economic and Monetary Union and Re-launching the Construction of Europe." Three papers were written by Alexandre Lamfalussy. Lamfalussy's articles dealt with some of the most important technical aspects of the process of monetary and economic union: the macro-coordination of fiscal policies in an economic and monetary union; the European Currency Unit banking market; and a proposal for centralizing monetary policy.

Back in the 1920s, Norman had mused to Benjamin Strong, the chairman of the New York Federal Reserve, about the need for a "private and eclectic Central banks' club, small at first, large in the future." When Norman had summoned Walter Layton, the editor of *The Economist*, to his office to ask him to draft the bank's statutes, he had emphasized that they must, above all, guarantee the BIS's independence. The Delors Report confirmed that crucial principle. Governments would be excluded from monetary policy

making. The Delors report called for the creation of a new institution to centrally decide and coordinate member states' monetary policy operations, to be called the European System of Central Banks (ESCB). Montagu Norman may not have approved of a Europe-wide currency, but he would certainly have applauded the report's demand that the ESCB must be completely independent from both national governments and European authorities.

The Delors Report's recommendations that the European Union should adopt a single currency and a unified monetary policy were accepted. The momentum toward monetary, economic, and political union was unstoppable. A new bank, the most powerful institution within the ESCB, would be created to define and implement monetary policy. The European Central Bank's primary task would be to ensure price stability while remaining free of all political pressures. It sounded all too familiar.

PART THREE: **MELTDOWN**

"European economic unity will come, for its time is here."

— Walther Funk, 1942[1]

The Reichsbank president and BIS director was half right. European economic unity did indeed arrive, but it came sixty years after he predicted. Walther Funk lived to see two of the most important early milestones: the establishment in 1951 of the European Coal and Steel Community, Europe's first supranational institution, whose loans were managed by the BIS, and the signing of the Treaty of Rome in 1957, when the six core countries—Germany, France, Italy, Belgium, Luxembourg, and the Netherlands—established the European Economic Community.

Funk was released from Spandau Prison in Berlin the same year and died in 1960, but his pan-European plan for a continent free of trade and currency restrictions lived on and flourished. A European customs union came into existence in 1968. Just over a decade later, in 1979, Europeans voted in the first elections for the European Parliament. In 1992 twelve European countries signed the Maastricht Treaty, which brought the European Union into existence. On January 1, 1993, the European single market began operating across the twelve member states of the European Union. Its citizens could live and work freely wherever they wanted, companies could sell their products, and currencies and capital flowed unhindered.

Funk would certainly have applauded. The Nazi economics minister had raised the idea of European monetary union as early as 1940, to be introduced incrementally by harmonizing currency fluctuations and constraining exchange rates, as indeed happened.

To point out any similarities between the Nazis' postwar economic plans for Europe and today's European Union is to risk ridicule and invective. The European integration project, has, for many, become an untouchable truth, an article of faith in the world's inexorable progress toward a brighter and more secure future. Certainly, European integration has many achievements to its credit: speeding up reconstruction after 1945; opening the continent for free trade and nurturing a new generation of pan-Europeans who think beyond national borders. By incorporating the shaky democracies of post–Communist Europe the European Union has helped stabilize the eastern half of the continent. The oft-stated values of the European Union: human rights, democracy, and protection of minorities are the very antithesis of the Third's Reich's ideology.

But it is a massive and illogical mental leap to claim, as did Helmut Kohl, the German chancellor, in 1996, "The policy of European integration is in reality a question of war and peace in the twenty-first century."[2] Kohl's statement embodies the technocrats' belief, reaching back to Jean Monnet and Montagu Norman, that the wise guidance of a managerial and financial elite is all that is needed for Europe to prosper—and to prevent its fractious, ungrateful peoples from reverting to their natural warlike state. The historian Antony Beevor makes a more convincing counterclaim: Western Europe has remained free of wars since 1945, not because of the European Union, but because of democracy. "It is simply a question of governance. Democracies do not fight each other."[3]

The uncomfortable, unspoken truth is that the parallels between the plans of the Nazi leadership for the postwar European economy and the subsequent process of European monetary and economic integration are real. The BIS runs like a thread through both. Funk's deputy Emil Puhl described the BIS

as the "only real foreign branch" of the Reichsbank, because it was the crucial connection of the Reichsbank to the international network of central bankers.[4] These connections outlived the war. The BIS helped ensure that the postwar successors to the Reichsbank, the Bank deutscher Länder, and the Bundesbank, would continue to dominate the economies of postwar Europe. The BIS provided the BdL and the Bundesbank with both legitimacy and prestige. The BdL, followed by the Bundesbank, took the Reichsbank's former place at the governors' meetings. The BIS gave the Bundesbank an instant network of connections to other central banks and a platform to shape the debate about the postwar European economy. Nor did the personnel change much: Karl Blessing, Schacht's protégé, worked at the BIS during the early 1930s, transferred to the Reichsbank, oversaw an empire of slave laborers during the war, then returned to the BIS in 1958 as the president of the Bundesbank.

During the 1930s and '40s, like the 1980s and '90s, the politicians laid out the general theory of European unification, while the technocrats—such as Funk—outlined the practical steps. As early as 1940, Arthur Seyss-Inquart, the ruler of the Nazi-occupied Netherlands, called for a new European community "above and beyond the concept of the nation-state," which would "transform the living space given us by history into a new spiritual realm."[5] The new Europe would benefit from "the most modern production techniques and a continent-wide system of trade and communications developed on a joint basis." Rapidly increasing prosperity was inevitable "once national barriers are removed."[6]

When Hitler called for the "clutter of small nations" to be removed, Funk readily agreed. "There must be a readiness to subordinate one's own interests in certain cases to that of the European Community."[7] The Reichsbank president laid out his thoughts in a detailed, eight-page memo called "Economic Reorganization of Europe," a copy of which is stored in the BIS archive in Basel. The document was translated by Per Jacobssen's staff and passed to Thomas McKittrick on July 26, 1940.[8]

All sorts of slogans were flying around about the "construction and organization of the German and the European economic system after the war," and the favorite was "European large-unit economy," noted Funk in his 1940 paper. Such a construct did not yet exist, but "the new European economy must be an organic growth" and will result from "close economic collaboration between Germany and European countries." The Reichsmark would be the dominant currency, but the currency basis of postwar Europe was of secondary importance to economic leadership. "Given a healthy European economy and a sensible division of labor between the European economies, the currency problem will solve itself because it will then be merely a question of suitable monetary technique." Here Funk seems to anticipate the arguments of the euro enthusiasts who, fifty years later, claimed that a common currency, if properly constructed in the right economic conditions, could not fail.

Funk's analysis and prediction are unsettlingly prescient of the subsequent course of postwar European economic and political history. The Reichsmark would be the dominant currency, and once it had been freed of foreign debt, its currency area must "continue to widen." Bilateral payments must be transformed into multilateral economic transactions and clearing arrangements, "so that the various countries may enter into properly regulated economic relations with one another through the intermediary of clearing arrangements of this kind"—just as happened with the 1947 Paris agreement on multilateral payments and its successor mechanisms, such as the European Payments Union (EPU).

Foreign exchange controls could not be abolished in one move or monetary union quickly introduced. The process must be incremental, Funk argued, anticipating the need for a halfway system like the EPU, which liberated non-residents from exchange controls, although they remained in place for citizens. "The problem is not one of free exchange or European monetary union, but in the first place, of a further development of clearing techniques for the purpose of ensuring a smooth course for payments within the countries participating in the clearing." The conversion rates must be controlled and kept stable. This was

also the aim of the Snake in the Tunnel and the European Monetary System, which were, like the EPU, managed or serviced which were, like the EPU, by the BIS.

An actual monetary union was more complicated, Funk presciently argued, as it demanded "a gradually assimilated standard of living, and even in the future the standard cannot be the same in all the countries participating in the European clearing"—a statement that neatly anticipated the modern disequilibrium between Germany and Greece. But once the European central clearing system was operating, foreign exchange restrictions would be abolished, first for travelers crossing frontiers and then for import trade. There would be a bonfire of regulations that slowed down trade and commerce; Funk wrote, "Meticulous surveillance and all the regulations, which weigh down on the individual business enterprise with a mass of forms, will no longer be necessary."[9]

Funk also predicted, correctly, that the future European currencies would not be linked to gold. The new multilateral monetary system would provide the necessary backing. The deciding factor in trade relations would be the quality of German goods for export, "and in this respect we really need have no anxiety." German needs would be central to the new European economy. Germany would reach long-term economic agreements with European countries so that they would plan their long-term production on the German market, and there would also be "better outlets for German goods on European markets."[10]

The Nazi leadership welcomed Funk's plans. In 1942, The German Foreign Ministry created a "Europe Committee," whose members drafted plans for a German-dominated European confederation. That same year the Berlin Union of Businessmen and Industrialists held a conference at the city's Economic University, entitled "European Economic Community." As the writer John Laughland notes, the titles of the speeches delivered at the conference are "eerily reminiscent of modern pro-European discourse." They include "The Economic Face of the New Europe," "The Development Towards the European Economic Community," "European Currency Matters," and the hardy perennial, still much discussed today: "The Fundamental Question: Is Europe a Geographical Concept or a Political Fact."[11] In June a German official drafted the "Basic Elements of a Plan for the New Europe," which outlined how the new confederation would work. Much of it sounds very familiar. The section entitled "The Economic Organization of Europe" called for a European customs union, a European clearing center that would stabilize currency rates with the eventual objective of European monetary union, and the "harmonization of labor conditions and social welfare."[12]

Germany's postwar remodeling of itself as a penitent bastion of democracy was predicted by Heinz Pol. Pol, a former editor of a Berlin newspaper, had fled from the Nazis to the United States. The BIS, wrote Pol, was a central pillar of this policy of expediency: the recognition that the war was lost, and Germany needed to make a deal with Allies that would preserve its dominance of Europe. During the war, both Hermann Schmitz, the CEO of IG Farben, and Kurt von Schröder, the Nazi banker, used their positions as BIS directors to keep channels open to the Allies, wrote Pol in his book, *The Hidden Enemy*, which was published in 1943. "Since the beginning of this war, both have maintained contacts, through go-betweens, with their business friends in all the countries of the United Nations."[13]

The OSS Harvard Plan documents detailing Thomas McKittrick's role in negotiating deals with German industrialists confirm Pol's assertion that the BIS was a contact point for negotiations about Germany's plans to dominate postwar Europe. Pol's predictions of how postwar German leaders would rapidly abandon the outward trappings of Nazism still make unsettling reading:

> *To obtain a peace, which would leave them in power, they will suddenly flaunt "European spirit" and offer worldwide "co-operation." They will chatter about liberty, equality, and*

fraternity. They will, all of a sudden, make up to the Jews. They will swear to live up to the demands of the Atlantic Charter and any other charter. They will share power with everybody and they will even let others rule for a while. They will do all this and more, if only they are allowed to keep some positions of power and control, that is, the only positions that count: in the army—were it even reduced to a few thousand men; in the key economic organizations; in the courts; in the universities; in the schools.[14]

Which is precisely what happened, when, after 1945 former Nazis took many of the key positions of "power and control" in the new Germany. Their legacy has proved extremely profitable. Germany now has the largest economy in the European Union and the fourth largest in the world. Greece faces collapse, and Spain is mired in recession, but Germany is booming, with growth rates of 3.7 percent in 2010 and 3 percent in 2011. Much of this success is based, as Funk predicted, on the high quality of German exports. Germany's total share of world trade is about 9 percent. The country is especially strong in the biotechnology, genetic engineering, and pharmaceutical sectors.

BASF and Bayer, two of IG Farben's successor companies, are dominant in their fields. BASF is the world's largest chemicals company with annual sales of 73.5 billion euros. Bayer, which makes aspirin, employs 112,000 people. Bayer felt no shame about its roots in IG Farben. In 1964 Bayer set up a foundation to honor Fritz ter Meer on his eightieth birthday with a donation of 2 million deutschmarks. Ter Meer had handled IG Farben's negotiations with Standard Oil and oversaw the building of IG Auschwitz. Found guilty of war crimes, ter Meer was sentenced to seven years imprisonment in 1948. He was freed in 1950 and later joined the supervisory board of Bayer. Bayer's foundation honoring him was renamed in 2005 and existed until 2007.

By the early 1990s, Funk's "European Large-Unit Economy," perhaps better known as the Eurozone, was clearly in sight. The technical preparations had been going on for decades—at least since 1964, when the Governors' Committee of European central banks had first met at the BIS to coordinate monetary policy, if not 1947, when the Paris accord on multilateral payments was signed. The positive reception for the 1989 Delors Report, which had been drafted at the BIS and which laid out the plan for EMU, meant that the political momentum was unstoppable.

In December 1993 Alexandre Lamfalussy stepped down as general manager of the BIS to start work as the director of the European Monetary Institute (EMI), the precursor of the European Central Bank. He would be much missed. "Lamfalussy put the BIS on the map. He was superb, very bright," said Geoffrey Bell, the founder of the G30 advisory group, an international think tank. "Lamfalussy was a thinker, especially when the bank started to move into intellectual issues such as bank regulation and the general state of the world."[15]

The EMI opened its doors the following month. Lamfalussy did not have far to go: the institute was based at the BIS. The president was charged with a mammoth task: the construction of the first trans-European monetary institution, in preparation for the introduction of the single currency. Nobody was better qualified for the job. Lamfalussy had been at the center of the drive to European monetary unity almost since its inception. The Hungarian economist had once boasted that it was his subordinates who "held the fountain pen" and "prepared the meetings in Basel of a project that was primarily European."

After eleven months, in November 1994, the EMI had outgrown the BIS and moved to Frankfurt. Its new home was a skyscraper at Willy-Brandt-Platz, known as the "Eurotower." The small number of staff that Lamfalussy brought from the BIS was not sufficient. The EMI president had to recruit 150 people in six months, and the network of contacts he had built up over seventeen years at the BIS was invaluable. "I knew everyone, and when I saw that there was a hole in the organization, or that we needed someone . . . I

knew exactly who to ask, and I could ask them for everything. It was a phenomenal advantage." Lamfalussy's network was also an advantage for the EMI's governors, he recalled, "because they also knew each other and the staff too."[16]

The Eurotower was forty stories tall, more than double the BIS's eighteen floors. The size of the Frankfurt skyscraper symbolized its role as the home of an idea that had been nurtured at the BIS but which had now far outgrown its birthplace. Nonetheless, the small, clubbable world of the Tower of Basel was soon replicated there. Back in the 1960s Charles Coombs, of the New York Federal Reserve, recalled that the central bankers at the BIS governors' meetings frequently did not even need to finish their sentences "because everyone instinctively knew the rest and in an almost uncanny way, a simultaneous realization of the appropriate technical solution." The EMI president enjoyed the same kind of telepathy with Hans Tietmeyer, the president of the Bundesbank, and Jacques Delors, the president of the European Commission.

When Europe's most powerful bankers and politicians came to Frankfurt to discuss the single currency project, Lamfalussy sat at the head of the table. "When Tietmeyer or Delors . . . would put up his hand to ask a question, I would know exactly what he would ask, and he also knew that I would know exactly what he wanted to ask. It was enough just to look at them and I knew what they wanted to talk about because I knew what they thought."[17]

THE DEPARTURE OF the EMI for Frankfurt left a void at the BIS. The long, looping corridors were quieter, the air of excitement that the bank was at the center of the most ambitious monetary project in European history had dissipated, and the chatter in the staff restaurant was more subdued. Even the Governors' Committee, which had met at the BIS since 1964, was gone. The committee's members—the governors of the European Central Banks—now formed the council of the EMI.

Once again, the BIS faced an existential crisis: Did it still need to exist? The bank was certainly still profitable. The accounts for the year ending March 1995 showed a net profit of 162.4 million gold francs. But if the BIS had no international role, it would be increasingly difficult to justify its existence and the extensive legal privileges that helped guarantee those profits. The bank had a new manager, Andrew Crockett, a British economist who had worked for the IMF from 1972 to 1989. Crocket came to the BIS in 1994 from the Bank of England, where he had spent four years as an executive director. There he could observe firsthand the after-effects of the "Big Bang," the 1986 deregulation of the City of the London.

Until the Big Bang, the Square Mile had been still a clubby, comfortable place of old school tie connections and long lunches, where Montagu Norman would have felt at home. That world vanished almost overnight. Wall Street investment banks poured into the Square Mile, bringing aggressive new tactics. The 1933 Glass-Steagall Act, which separated investment banking and deposit taking, was still in force in the United States. London, newly unburdened from cumbersome regulations, offered fabulous opportunities, heightened by the rapid growth of computer technology, which accelerated trading. The BIS gave the Big Bang a cautious welcome. "It was feared that if nothing was done, the Stock Exchange would be unable to compete with foreign institutions and business would move abroad," the BIS noted in its 1987 Annual Report.[18] The changes had brought a "major inflow" of capital to British and foreign banks, the BIS noted, but had highlighted the importance of Chinese walls within firms to avoid conflicts of interest. The Chinese walls however, soon crumbled under the tsunami of money. The city firms' new American partners often had few qualms about conflicts of interest. They advised a company on a merger, and then sold the new shares.

Some said that the BIS job was Crockett's consolation prize for his failure to get the top job at the IMF. Either way, he had not joined the BIS to see it fade away. Crockett's international background

brought valuable perspective to what could still be a cozy and parochial institution. Crockett understood that the establishment of the EMI marked the end of an era for the BIS. The bank was sixty-four years old, of pensionable age. Its original mission, of managing German reparations payments from the First World War, had long faded away, the details of the arcane disputes preserved in dusty files in the bank's archives.

Suddenly the BIS looked like an anachronism, a hangover of the era of credit controls and currency restrictions in a global economy that was ever more interlinked, dynamic, and faster moving. Small, unimportant countries such as Belgium and the Netherlands sat on the board, but where were the central banks of China, Brazil, Saudi Arabia, and Russia? True, Japan, Canada, and Turkey had joined, but many, especially in the United States, regarded the bank as a thoroughly Eurocentric institution. William White, from the Bank of Canada, joined the BIS in May 1995 as head of the Monetary and Economic Department, the bank's research arm. "When I arrived, people were asking what is the BIS going to do after the euro? It was a legitimate question. It was a very heavily European organization. Once the EMI was set up, all the Euro stuff was going to get done somewhere else."[19]

The BIS had to find a new purpose. To Crockett it was clear, White recalled. "Crockett said, we are going to go global." But for that to happen, the United States needed to be on board. More than sixty years after the BIS was founded, the Federal Reserve still kept its distance and had not taken up its tranche of shares, despite the BIS's deep American roots. The United States had always followed what was happening at the bank and the discussions taking place there. But the American Federal Reserve officials who traveled to Basel were there as observers, not as representatives of a member bank. Crockett wanted to end this anomaly. All the countries that took part in the G10 Sunday evening governors' meeting at the BIS should be members of the bank and be represented on the board of the bank, he believed. The Federal Reserve needed first to join the bank, then the board.[20]

During the 1970s and '80s, Washington had not been especially interested in the BIS. The focus then had been primarily on trade, rather than finance, said Karen Johnson, a former Federal Reserve director for International Finance. "Trade behaves in a rather predictable way. It's hard to change, but it's also hard to surprise you. That began to alter in the 1980s and changed hugely in the 1990s." Rapidly increasing globalization, the growing power of international markets and money's ability to flow ever faster around the world highlighted how the United States economy was inextricably linked to the global financial system. "Financial linkages had become vastly more important. The actions occurring in the financial markets were much faster. Crises or unanticipated events were far more likely to occur on the financial side," said Johnson.

Crockett's lobbying worked. In 1994 the Federal Reserve finally took up its shares in the BIS, joined the bank and appointed two directors to the board: the chairman of the Federal Reserve and the president of the New York Federal Reserve. The decision to join the board was made, noted Charles J. Siegman, a senior official in the Federal Reserve's International Finance Division, "in recognition of the increasingly important role of the BIS as the principal forum for consultation, cooperation and information exchange among central bankers and in anticipation of a broadening of that role."[21] The American decision sent a powerful signal to the world suggesting that the BIS was still relevant, necessary and could contribute to international financial stability. Two years later, in 1996, the central banks or monetary authorities of China, India, Russia, Brazil, Hong Kong, Singapore, and Saudi Arabia joined. The BIS's future was assured.

As director of the Division of International Finance, Karen Johnson attended the governors' meetings for nine years, from 1998 until her retirement in 2007, accompanying either Alan Greenspan, the chairman of the Federal Reserve or his successor, Ben Bernanke, or their deputies. Johnson successfully pushed for

the Federal Reserve to pay attention to the BIS. "The American attitude to the BIS changed because the world changed. The BIS was expanding its membership because countries in the rest of the world now mattered in ways they hadn't mattered before. The BIS went from being a Eurocentric thing to which the United States paid little attention, to something global and international. Once we took up our shares the degree to which senior members of the Fed became involved changed completely."[22]

The Federal Reserve and the New York Federal Reserve, like all visiting central banks, opened up a micro-branch in the BIS headquarters during the Basel weekends. Both had their own offices, as well as a shared extra room for staffers or other governors who might also be attending. Johnson enjoyed her trips to Basel. From Stanford University, she had joined the Federal Reserve in 1979—a rare woman in the male-dominated world of central banking. "Going to these international meetings, I was again the only woman in the room, but because I had the Fed on my nametag, that opened every door I wanted."[23]

IN JUNE 1998, four years and five months after Alexandre Lamfalussy left the BIS to set up the EMI, it was closed down—a mark of its success, rather than its failure. The European Central Bank opened for business. Seven months later, on January 1, 1999, eleven countries launched the euro. Technically, the birth of the single currency was an extraordinary achievement, justly earning the former BIS manager the title of "Father of the Euro." The euro finally replaced national currencies in January 2002. The press coverage, much of which was jubilant, focused on the benefits. These were considerable, at least in terms of convenience and ease of monetary transactions, and markedly similar to those predicted by Funk in his 1940 memo. Travelers could use the same currency from Portugal's Atlantic coast to Finland's Arctic border. So could companies trading in the Eurozone. Bank charges for European foreign currency accounts, commission on changing currencies, cumbersome record keeping, all these vanished instantly. The Stability and Growth Pact, signed in 1997, would theoretically ensure budgetary discipline and keep the currency stable. National budget deficits would not be allowed to exceed three percent of GDP.

Among the jubilation, less attention was paid to the political aspects of the single currency. Once again, the creeping removal of national sovereignty was portrayed as a fundamentally technocratic innovation, rather than a political decision—as indeed had been the case since the establishment of the European Coal and Steel Community in 1951.

When a country joined the Eurozone, its central bank automatically became part of the European System of Central Banks, whose centerpiece was the ECB. The member country surrendered control over its monetary policy, although it was represented on the ECB's Governing Council. There was logic to this: a common currency would soon go out of business if each member state were running an independent monetary fiefdom.

In London the idea of surrendering monetary sovereignty was regarded with horror. In Washington, DC, Paul Volcker took a more nuanced view. He supported the idea of a European Central Bank, but still thought, "It was a very peculiar thing to have a central bank without a government."[24] The chairman of the Federal Reserve could see the reasoning behind a single bank and currency but thought that they needed to be properly integrated with fiscal discipline. "There were negative factors as well as positive ones. Someone was always devaluing a currency. Then they would make attempts to stabilize it, and then it would fall apart. So it made sense to me to have a common currency if you are having a lot of problems. But it was too optimistic to think that the mere fact of a common currency would force discipline on individual members because they could no longer devalue their currencies."[25]

For many, it seemed that the introduction of the euro was, in part, a continuation of the Second World War by other means. The real issues were not monetary, but political. French politicians believed that the single currency would solve the German problem forever. Twice in a century Germany had laid waste to

Europe. But now that Germany was locked into the European integration project, or even shackled to it, it would neither want, nor be able to go to war again. Germany's future and prosperity would be inexorably linked to that of its most important neighbor and rival: France. Of course, national rivalries would continue, but the Germans would be part of a trans-European currency that would dilute their monetary sovereignty and finally lay the ghosts of the Second World War to rest. The French believed—erroneously as it turned out—that Berlin would no longer be able to dominate the European economy. In fact, for the Bundesbank shaped the design of the ECB, ensuring that it was focused on price stability, and retained enormous influence over the ECB's operations.

The creation of the euro was a political compromise, said Zsigmond Jarai, a former governor of the National Bank of Hungary and minister of finance. "France let Germany unify in 1989. But France was worried that a unified Germany would dominate the whole continent and would be too strong. So Paris said, OK, you can unify but without the deutschmark, and we will have the euro instead. The German accepted and also won a new market in Eastern Europe for their exports." The deutschmark was the basis of the euro, said Jarai. "The aim was to export German economic stability to France and Italy. The deutschmark was always the strong currency, and the Bundesbank was the bank that could control inflation. France and Italy were unable to do that. The aim was to use the ECB to force France and Italy to keep their money under control."[26]

The new currency, intended to symbolize a new era of European cooperation was really a means of settling old scores, said Rupert Pennant-Rea, who served as deputy governor of the Bank of England from 1993 to 1995.

> *The euro was a monstrous creation. It was driven by the politics of the Franco-German relationship, which had its obvious echo in the relationship between the Bundesbank and the Bank of France, where, on the whole, what the first did the second did immediately afterward. The French political class hated the fact that they had to dance to the Bundesbank's tunes. You could argue that, from a French point of view, the euro was little more than a way out of that continuous insult to their national pride. The French felt they were more or less equal with the Germans on most subjects, but on monetary issues they were always, always second and subservient. They hated that.*

AND FOR ALL the technical expertise supplied by Lamfalussy and his BIS-in-exile in Frankfurt, the project was doomed from the start, the British former central banker argued. "It was completely misdesigned. You should not create a monetary union of such disparate economies because it doesn't work. There were a lot of economists saying that, but the politicians said we know better, we are creating history. We have an evangelical legitimacy which you mere mortals don't understand."[27]

Why, then, did the Germans agree? The Bundesbank, said Pennant-Rea, always hated the idea of the euro, because it clearly saw that monetary union would dilute German monetary sovereignty. But Chancellor Helmut Kohl, President François Mitterrand, and Jacques Delors were fixated on their place in the history books. The loss of monetary sovereignty was a small price to pay for redesigning a continent—to a plan drawn up in Berlin as much as Paris and Brussels. "I think it was a matter of great men and their moment. This is us creating the new Europe, where all that ghastly history of the last century we can now firmly say is gone and will never return, because we have now created something utterly different. But that bore no relation to what the great majority of the German people were thinking or wanted, their leaders never tested public opinion. It was horrific."[28]

Whatever his inner doubts, Lamfalussy got on with the job of making the euro happen. The Hungarian economist was a modest and likeable person, said Pennant-Rea. "He was trying to find the truth in the economics of it. But he was working on the creation of the euro in a highly politicized environment, trying to be faithful to his economic analyses and not let the politics turn his head."

Even those more sympathetic to the project admit it was flawed from the outset. The Eurozone had two inherent flaws. First, it was not a homogeneous currency area. Uniting countries as diverse as Germany and Greece—or Italy or France for that matter—each with different cultures, histories, economic and fiscal policies, and attitudes toward the role of the state and rights to raise taxes was always going to be a hazardous enterprise, as indeed Walter Funk had predicted in 1940. Second, the Eurozone needed a credible transnational fiscal system, with rules and an enforcement mechanism, as Lamfalussy had argued. National governments in the Eurozone retained the rights to raise taxes and control their public spending, even though those decisions ultimately impacted on the other members. Thus all the Eurozone members were, in effect, held hostage to each other—with no means of controlling those outside influences.

The counter argument is that the momentum toward full union was now unstoppable. The euro was a currency whose time had come. Like Hjalmar Schacht's rentenmark that was introduced to wipe out the hyperinflation in the 1920s, or the deutschmark that was brought in to stabilize the postwar economy, the euro would work, or have to work, because enough people, especially among Europe's ruling class, believed that it would. And the euro was always about more than a common currency. The introduction of EMU, the technocrats believed, would somehow force a resolution of the euro's contradictions and then catalyse the process of full European monetary, economic and political union. "The member countries of the Eurozone and the European Union have always used somewhat narrow decisions about economic structure to try to build a broader political economy in Europe," said Malcolm Knight, who served as BIS manager from 2003 to 2008.[29]

In other words, technical decisions about financial and monetary policy have been used to introduce the supranational state by stealth—often via the BIS. The warnings about the single currency's contradictions went unheeded and Europe is now paying the price. Some of the Eurozone's problems should have been foreseen, argued Nathan Sheets, who served as head of the Federal Reserve's division of International Finance from 2008 to 2011. "When they drew up the treaties, they didn't have any B-plans. They made it impossible for somebody to leave or be expelled. There are no clear mechanisms for dealing with a country whose sovereign debt is under stress. There was an insufficient commitment to surveillance and making sure people stayed within the rules."[30] These flaws were exacerbated by the subsequent expansion of the Eurozone to seventeen members. "They started the Eurozone with a very heterogeneous group of countries and then they made it even more so by bringing in those additional countries."[31]

It was obvious from the outset that the euro could not work, said Zsigmond Jarai, who attended numerous meetings at the BIS and was well acquainted with his compatriot, Alexandre Lamfalussy. "Before the crisis, Lamfalussy told me, because it was clear to everybody, that if you have a common currency you have to have a common economic and fiscal policy from the beginning. Lamfalussy told me that the idea was they create the currency first and that will force the creation of a more common economic and fiscal policy."[32] Europe, however, is still waiting.

"I had a file six inches thick on Freddie Mac and Fannie Mae."

— William White

The BIS's decision to collect statistics on international banking activity and computerize its data repository had paid handsome dividends. The bank rapidly became one of the best-informed financial institutions in the world, especially about cross-border banking transactions and the flow of international capital. Commercial banks, including some that were domiciled in off-shore financial centers, supplied data on their assets and liabilities and foreign currency and cross-border transactions to a central banking authority—usually the national bank or its equivalent—which aggregated the data and forwarded it to the BIS. The bank then published some of the information in its *Quarterly Review*. The BIS had been designed as a bank for central banks. But agile as ever, it had remodeled itself as an essential point of reference for information on the commercial banking sector and all that flowed from that.

The *65th Annual Report*, covering 1994–1995, was 228 pages long and was a veritable encyclopedia of economic and financial statistics and indicators. It covered international trade in both the Western and developing world: monetary policy, bond markets, exchange rates, capital flows in emerging and Western markets, and developments in international financial markets. It offered summaries, analyses, and guidance, and called for greater cooperation and coordination between banks and regulatory authorities.

When William White arrived in Basel from Ottawa in 1995, he took over a highly regarded economic research department. The bank's prescriptions had remained more or less constant since Per Jacobssen had arrived in 1931 and written the first reports: tight control of credit and the need to control inflation. "If there is one thing that distinguishes the BIS way of looking at things from virtually everybody else," said White, "it is that they do put more emphasis on the bad things that can happen from excessive lending. That goes back to the 1930s and the bank's founding after the hyperinflation in Germany."[1]

The bank had warned about the excessively easy credit that was fueling the Asian economic boom during the 1990s. When the Asian debt crisis exploded in 1997 and the Thai baht collapsed and spread contagion across the region, the BIS was vindicated, although that was meager comfort. "People said the Southeast Asian debt crisis came out of nowhere and was impossible to predict," said White. "This is all nonsense. The BIS banking statistics made it very clear in the 1990s that huge amounts of money were being borrowed in foreign currencies for very short terms, then being lent out in domestic currency at much longer maturities. The Asian debt crisis was an accident waiting to happen."[2]

Knowing there was a problem, however, did not mean the bank could always persuade policymakers to take preventative or remedial measures. Just a few years later, in the early 2000s, the United States was also facing a similar potential financial meltdown. The repeal in 1999 of the Glass-Steagall Act that separated banks' deposit taking and broking activities had helped fuel a credit boom and asset bubble. Glass-Steagall had been passed in 1933 during the Great Depression. The warnings of those who said that repealing the act would trigger another cycle of boom, bust, and depression were ignored.

BIS officials were especially concerned about the Federal National Mortgage Association (FNMA), known colloquially as Fannie Mae, and the Federal Home Loan Mortgage Corporation (FHLMC), known as Freddie Mac. The two institutions were government enterprises that provided liquidity to the mortgage

system. They purchased home loans, providing the loans met their criteria, and turned them into mortgage-backed securities. Freddie and Fannie then sold the securities to outside investors and guaranteed both the principal and the interest payments. Thanks to the government's imprimatur, the system worked and remained stable.

But in the early 2000s, Wall Street worked out how to purchase and securitize mortgages without going through Freddie or Fannie. Finance houses such as Lehman Brothers and Bear Stearns bundled high-risk subprime mortgages—those granted to borrowers with a poor credit rating—into securities. The Wall Street finance houses then sold them to investors, few of whom understood the risks they were buying.

The global credit system was vastly overstretched. The BIS had repeatedly warned that excessive global credit growth, poor lending practices by commercial banks, private sector excesses and global imbalances were fueling a potential crisis. But as rivers of easy money flowed around the world, it seemed nobody was listening. BIS officials did not consider Freddie and Fannie to be a contaminant of global markets. Rather, they were a potential trigger for disaster. The central bankers needed to take notice. The place to discuss Freddie and Fannie was the BIS Committee on the Global Financial System. The committee, composed of deputy governors of central banks and other officials, was charged with analyzing and responding to stress in global financial markets. But it seemed that the central bankers did not want to talk about Freddie and Fannie. The issue was considered politically untouchable.

The United States was not the only country with powerful and risky government-sponsored enterprises —commercial companies backed by the state. France had its Caisse des dépôts et consignations, a state development and investment fund; each German state had its own bank, known as a Landesbank, and Japan offered banking services at its post office. The combination of state guarantees for commercial risks was potentially explosive, whether in Tokyo, Toulouse, or Texas. Attempts were made to get the committee to consider the whole question of government-sponsored enterprises, without focusing attention on any one country. These too, failed.

Long after he left the Bank of England, the BIS annual reports remained essential reading, said Rupert Pennant-Rea.

> *The BIS started warning about the problems with excessive credit growth, excessive interconnectedness and some of the other major frailties in the financial system back in 2003 or 2004. Everybody says nobody foresaw 2007–2008; that's not true. One organisation that did was the BIS. Not in every detail. But in terms of warning, that things were going wrong, that there was far too much debt on every sector's balance sheets, that banks were in a very dangerous interconnected area, with positions against each other and overleveraged, a lot of that is in those rather dull looking annual reports.*[3]

The work of hosting the BIS committees is less glamorous than, for example, preparing for the governors' meetings. But in the long-term the committees are at least as useful for the bank: the BIS has made itself a central, indispensable pillar of the forums dealing with the most important questions about the global financial system. Every year more than five thousand senior executives and officials from central banks and supervisory authorities travel to Basel. The bank organizes specialist gatherings on topics including monetary and financial stability, reserve management, information technology, and internal auditing. Over the years the BIS has made itself the central hub for the world's central bank governors and their staffs.

Among the bank's six committees, only the Basel Committee on Banking Supervision that deals with commercial banking supervision, usually receives media attention, as its work directly affects the public that hold their accounts in commercial banks. The aim of the Basel Committee, as it is usually known, according to the BIS website, is to "enhance understanding of key supervisory issues and improve the quality of banking supervision worldwide."

PARADOXICALLY, THE INCREASE in globalization was highlighting national banking disparities. Not only banking supervision standards varied from country to country, but so did the definitions of capital assets. Some banks counted long-term debts and off-balance sheet items as assets, while others did not. In 1988 the Basel Committee drew up new rules, which said, in essence, that bank capital must equal at least 8 percent of its assets, including its loans and liabilities. If a bank did not have sufficient capital, it must reduce its liabilities and risk exposure. The committee has no powers of enforcement, but it does have enormous moral authority. Any bank wishing to operate on international markets must adhere to the 8 percent rule.

Basel I, as the 1998 accord is known, has continued to evolve. Basel II, published in 2004, further honed and regulated capital requirements, quantified risk, and standardized international regulations, so as not to create competitive inequality, meaning that customers search for banks with looser controls. Regulating capital requirements while leaving banks free to lend is a delicate balancing act, said William McDonough, who served as chairman of the New York Federal Reserve from 1993 to 2003, and chaired the Basel Committee from 2000 to 2003. "One recognizes that there is an inherent conflict. The avoidance of financial crises is the public good, so for that a higher capital requirement is better. On the other hand, the whole capitalist free market system works by the savings of some being transferred and made available for the investment of others. So there has to be a trade where one does the best one can."[4]

Looking back with hindsight at the economic crash of late 2007, it is clear that the capital requirements of Basel II were insufficient, said McDonough. "The aim of Basel II was to bring up capital requirements but to do so in a way that would not stifle the world economy. In the event the rules were not as strong or as fine-tuned as they needed to be when the crisis came."[5] The Basel III accords, which have not yet been implemented, aim to further hone the regulations governing banks' capital requirements.

No matter how dedicated the regulators are, they are always behind the traders. McDonough said, "We did not anticipate the blowing up of the exotic instruments that brought down Lehman Brothers and the spin effect that resulted from that. If it had been, then hopefully somebody would have tried to avoid it."[6] But the regulators, like generals, are inevitably fighting the last battle. Capital moves faster, the global economy is ever more entwined, and financial instruments are more complex. Each time a new set of rules is issued, Wall Street hires the best and brightest financial and legal brains to find a way to push compliance to new limits. Despite its legions of experts, the BIS was unable to predict or prevent the Libor scandal, when commercial banks made vast profits by manipulating interbank lending rates for their own advantage. The Basel banking accords did not deal with Libor.

For all its endorsement of good bank governance, the BIS has been criticized over its own commercial actions. The BIS's main shareholders have always been central banks, but after the bank was founded in 1930 some of the original shareholders—US, French, and Belgian banks—sold part of their holdings. At the end of 2000, almost 14 percent of the BIS's capital, 72,648 shares, was still in private hands and being traded. The BIS announced that it would buy back those shares in a compulsory re-purchase. Thanks to the BIS's legal status, the decision could not be contested. But the price could. The bank offered 16,000 Swiss francs per share.

Three shareholders refused to accept the price. It was around twice the shares' trading price but still

less than the shares would be worth if valued as a proportion of the net asset value of the bank, they argued. First Eagle Funds, a New York–based group of mutual funds, and the other two, small private investors, took the case to the Hague Arbitral Tribunal, which governs disputes with the BIS. The tribunal ruled in their favor. It said that the BIS had miscalculated the shares' value. The tribunal awarded the private shareholders an extra 7,977.56 Swiss francs per share, plus 5 percent interest, bringing the total extra to 9,052.90 Swiss francs—over 50 percent more than the original offer.[7] The decision, noted the *Central Banking Journal*, was a "humiliating rebuff" for the board of directors who had signed off on the original price, including Jean-Claude Trichet, chairman of the Federal Reserve Alan Greenspan, and the governor of the Bank of England Sir Eddie George.[8]

The problem was not the compulsory squeeze out of private shareholders, said Charles de Vaulx, then the portfolio manager of First Eagle Funds, and now chief investment officer and portfolio manager at International Value Advisers. "I could understand that it was an accident of history that the shares happened to be listed, and the bank wanted to buy them back. But the price has to be fair. A squeeze-out deal, which is compulsory, has to have higher standards. The supreme irony is that the BIS has always portrayed itself as promoting proper capital adequacy, transparency, corporate governance, all these good things, which make the world a better place. But when it came to buying back their own shares, why aren't they holding themselves up to the same standards?"[9] Andrew Crockett, the BIS's general manager from 1994 to 2003, said at the time that he believed the offer was "fair" based on the valuation by J. P. Morgan.[10]

MEANWHILE, IN FRANKFURT, the European Central Bank flourished. The ECB is now one of the world's most powerful central banks. It manages monetary policy for seventeen Eurozone members, an area that reaches from the Atlantic coast of Portugal to the Turkish frontier, and which is home to more than 330 million people.

The influence of the BIS, the ECB's parent bank, is clear. The ECB is an ultramodern, even a postmodern institution—as Paul Volcker noted—a central bank without a country or national reserves. It is the ultimate financial expression of Jean Monnet's supranational dream. But the ECB's founding ethos is firmly rooted in the Norman-Schacht era. Its structure, modus operandi, and lack of accountability mirror that of the BIS. Like the BIS, the ECB is rigorously protected by international law, in its case the Maastricht Treaty that founded the European Union.

This is partly because the ECB was always a political as much as a monetary construct, rooted in trade-offs and behind-the-scenes deals. As the most powerful central bank in Europe, the Bundesbank was extremely influential in the design of the ECB. The Bundesbank ensured that the ECB's "primary objective," as the ECB notes on its website, is to "maintain price stability" with inflation rates below 2 percent.[11] (The Federal Reserve, in contrast, has a dual mandate of combating unemployment and inflation.) "The Germans take a very narrow view of the proper role of central banks, that it is to do almost exclusively with the preservation of price stability," said William White. "That comes from their history and experience of hyperinflation."[12]

To whom then is the ECB democratically accountable? In effect, nobody. The ECB's Governing Council has direct control over the tools of monetary policy. It is prohibited from taking advice from Eurozone governments.[13] The European Parliament has no meaningful authority over the ECB. "The ECB enjoys an extraordinary amount of independence," wrote Professor Anne Sibert, an expert on bank governance, in a 2009 paper. "It has an unusual amount of target independence; its degree of operational independence is probably unprecedented; it is almost completely financially independent; it is nearly

functionally independent," meaning that the ECB has control over most instruments of monetary policy and the freedom to use them as it sees fit.[14]

The ECB does issue a press release after the monetary policy meetings of the Governing Council, detailing any changes in bank rates and the ECB's president holds a press conference. The bank also publishes a monthly bulletin. But this is the bare minimum of reporting requirements – and a long way from proper accountability. Like the BIS, the ECB keeps its inner workings secret. "The ECB lacks transparency, especially procedural transparency," noted Professor Sibert. "We do not know how decisions are reached; it appears that votes are not even taken. Press conferences are no substitute for a failure to publish minutes."[15]

The US Federal Reserve issues a press release after each meeting of the Federal Open Market Committee (FOMC). The release includes the vote of the FOMC and the views of any dissenters. After each meeting of the FOMC, the minutes of the previous meeting are released, with a detailed summary of the reasons for the policy decisions taken. The Federal Reserve is accountable to Congress. The bank's chairman appears twice a year before Congress, and before each appearance the board submits a comprehensive report. It is a meaningful, comprehensive analysis, taking in the interconnections between monetary and fiscal policy and the impact of the Federal Reserve's decisions. The Bank of England also publishes the minutes of its monetary policy meetings, with a two-week delay.

The European Parliament has passed repeated resolutions demanding that the ECB publish the minutes of the Governing Council meetings and to release a summary of the vote, without naming names. The central bank governors who are members of the ECB's governing Council use the same arguments as to why this should not happen as those advanced by BIS officials for not releasing any minutes of the governors' meetings: that they would limit the free exchange of ideas at the meeting. The minutes of the ECB Governing Council might also reveal, how despite the ECB's claim to be above national politics, the governors of member central banks can still put their home countries' interests before those of the Eurozone as a whole.

ECB officials argue that the European Parliament's lack of power over the ECB does not take into account its specific role as a unique, supranational bank. "This does not imply that the ECB might be less accountable than the other central banks . . . it merely points to specific features of the European way of holding the bank accountable."[16] The ECB says that it enjoys "input legitimacy," as an institution established through the treaty that brought the European Union into existence. However "input legitimacy" is less impressive than it may sound. As the crisis in the Eurozone has worsened the ECB's "input legitimacy" has steadily evaporated.

In a nod to democracy, it was decided that the Maastricht Treaty needed to be ratified by all twelve EU members. But only three of the signatories trusted their citizens sufficiently to hold a referendum. Perhaps the politicians anticipated the results. Denmark narrowly rejected the treaty in 1992, with 50.7 percent voting no. France stunned the federalists when just 51 percent of the population voted in favor. Only Ireland was enthusiastic, with a 68.7 percent vote. The remaining nine members delegated the vote to their parliaments, all of which approved the treaty. Denmark voted again the following year. Copenhagen negotiated four opt-outs from the treaty, including the right not to join the European Union. This time the yes vote won, with 56.7 percent.

The ongoing experience of European union seemed only to dampen its citizens' enthusiasm. In 2005 France and the Netherlands both voted no in referenda on the new European constitution, which would have replaced previous treaties and further accelerated the federalization process. European officials then stepped around this by renaming the constitution as the Lisbon Treaty and arguing that it merely amended previous treaties—thus there was no need for referenda. Only Ireland held a referendum on Lisbon, in

June 2008, when 53.4 percent voted no. After sufficient political and pressure was applied, a second referendum was held in October 2009. This time Irish voters voted yes.

The more the European politicians and officials talked of democracy, it seemed, the less the citizens of the continent were able to exercise it. But the course of events in postwar Europe had been decided decades before the ECB opened for business.

Back in October 1941, Thomas McKittrick had received an inquiry from a friend of his living in Louisville, Kentucky, asking about the plans for the postwar financial system. The BIS president replied, "People everywhere are talking about federalisation accompanied by partial abrogation of national sovereignty. . . . The extent to which national sovereignty in this direction is limited must fix the boundaries of international financial authority."[17]

For Europe at least, those bounds were now fixed, permanently, at the ECB's headquarters in the Eurotower at Willy-Brandt-Platz, in downtown Frankfurt. But despite the technocrats' best efforts, real life was proving more complicated than the bank's monetary framework for the new Europe. Germans saved; Greeks spent. Italians did not pay their taxes. The French refused to give up their six-week holidays. Germany and France both broke the Stability and Growth Pact's rules governing public debt. But some things were immutable. The ECB's price obsession, engraved in its statutes, to keep inflation below 2 percent, forced Eurozone governments to slash public services and cut public spending. That in turn reduced consumer demand, stalled economic growth, increased unemployment and triggered a slide into recession that has resulted in Europe's gravest political and economic crisis since 1945.

AS THE GLOBAL financial crisis deepened, the politesse at the BIS governors' meetings began to crack. There is no formal policy coordination at the bimonthly gatherings, but the central bankers try to harmonize their monetary policies for maximum benefit where possible. Yet, paradoxically, as the world's economy has become more globalized, central bankers are turning to local solutions. It has become clear that since the crash of 2007 the governors—who, after all, govern *national* central banks—will work to protect their countries' interests first, even if that has deleterious effects on other nations' economies.

Insiders have said that the divide between those countries that shape the global economy and those that are buffeted by decisions taken in Western capitals is now ever more evident at the Global Economy Meetings. The United States, Japan, and Britain have been injecting trillions of dollars' worth of liquidity into their economies to try and boost growth. The theory is that asset purchases known as "Quantative Easing" will boost commercial banks' balance sheets, increase liquidity, and encourage more lending, which will in turn boost spending, growth, and create jobs. At the same time, the United States, Britain, Japan, and the European Central Bank are implementing a loose monetary policy of ultralow interest rates.

This results in an outflow of hot money, chasing better returns around the world, which causes asset bubbles in the destination economies and distorts exchange rates, making currencies such as the Malaysian ringgit and the Korean won more expensive and thus affecting exports from those countries. "The disagreements on this were more pronounced," said a former central banker, who wished to remain anonymous, of the governors' meetings in late 2012. "Most of the developing countries were saying, 'We don't see that low interest rates are adding to your economic growth and at the same time it causes us problems because of the capital inflows. Our exchange rates go up and we are having real estate bubbles.'" The central bankers remain polite. "Everyone is very careful because you cannot tell other countries what to do. But the developing countries are saying, look, this is what these policies are doing to us. They are causing us problems."[18]

Much of the criticism was directed at the United States, with the main complaints coming from Southeast Asian countries and some Latin American countries. "The more successful they are, the more upset they are. This policy is creating large capital flows into these developing countries, which they don't necessarily need." The governors at the Global Economy Meeting never speak publicly about the discussions that take place inside the BIS, but similar debates are happening in other fora, where they feel less constrained. In December 2012 Glenn Stevens, the governor of the Reserve Bank of Australia, gave a speech in Bangkok that was seen as a barely veiled attack on the Federal Reserve, the Bank of Japan, and the European Central Bank. Stevens even accused the three of "exporting their weaknesses" in language unlikely to be used at a governors' dinner.[19]

But there was more optimism about the euro. "Everyone was waiting for Mario Draghi's magic touch," said the former central banker. A Greek exit from the Eurozone looked less likely. Bailout funds were being released, and Greece's fiscal targets were being relaxed. The European Stability Mechanism (ESM), the 700 billion euro rescue fund for Greece, Ireland, and Portugal, is now a permanent institution. Mario Draghi did, indeed, seem to have a "magic touch." By stating that the ECB would do "whatever it takes" to stop the euro breaking up, and by stating that the bank was ready to buy "unlimited amounts" of short-dated bonds of indebted countries provided the country met certain conditions, the bank's president reassured the markets. Spain and Italy's borrowing costs quickly fell.

Draghi's plan was a move of "genius," according to the former central banker. "The ECB says it will buy debt, but the conditions the bank has imposed make it next to impossible for it to actually make the purchase. But the market applauds them and says all the problems are solved. This is the ultimate result that a central bank can achieve. You say something, and without doing anything, without spending one cent, you totally change the market sentiment. Every central banker dreams of this. It is close to a miracle."[20]

DRAGHI WAS NOT the only central banker basking in media attention. Central bankers are now the rock stars of the financial crisis. The men—they are nearly all men—in sober suits have "achieved a new prominence and become pivotal members of the policy-making establishments of both national and intergovernmental organizations," noted a report co-authored by Ernst & Young, a financial consultancy, and the Official Monetary and Financial Institutions Forum (OMFIF), a forum for central bankers and regulators.[21] The financial crisis and the subsequent need for rapid, coordinated global responses have blurred the traditional distinction between governments' fiscal policies (taxes and public spending) and the central banks' mandate of monetary policy (interest rates and control of inflation). In many countries, central bank governors are "as well known as the government leaders they serve, and their words and deeds are the subject of heated debate in newspapers, bars, and taxicabs."[22]

When Mark Carney, the governor of the Bank of the Canada, was appointed governor of the Bank of England in November 2012, he received the kind of media coverage usually reserved for royalty and soccer players. The *Sunday Times* newspaper ran a hagiographic profile, under the headline "A Superhuman to Push the Old Lady," meaning the Old Lady of Threadneedle Street in the City of London, a synonym for the Bank of England. Carney, who is trim and photogenic, was the first foreigner to be appointed to the job since the bank was founded in 1694. The article enthused that he had "charm, talent, and [George] Clooney looks." He even had a social conscience and had made understanding noises about the Occupy Wall Street movement.[23] This winning combination brought Carney a salary package worth around $1.4 million per year, and he will enjoy a substantial expansion of powers: the bank will now have regulatory control over Britain's commercial banks and insurers.[24]

Carney is a well-known figure at the BIS. He is a member of the board, representing the Bank of Canada. He has served as chairman of the BIS Committee on the Global Financial System, which is a forum for central banks to coordinate polices on monetary and financial stability. He is also chairman of the Financial Stability Board (FSB), which coordinates international financial supervisory and regulatory policies. The BIS hosts the FSB, and insiders say it is likely to assume increasing importance, reflecting the growing mandate of central bankers. Some are now required to supervise national commercial banks, oversee risk management and national financial systems, and stand ever ready as a backstop should disaster strike. "The idea that central bankers should have a primary responsibility for financial stability, as well as price stability, was considered a pretty dramatic break with orthodox central bank thinking, especially in the United States," said Malcolm Knight.[25]

Carney's years at the BIS have brought him a priceless network of personal relationships, nurtured at the bank's dinners and lunches. These connections and the mutual trust that grows between the central bankers fostered by the BIS "matter a great deal," said Sir Mervyn King. "They bring personal trust and confidence, which is very important. Finance ministers do not have the same length of tenure and so do not get to know each other so well."

The governors' personal relationships are crucial in times of crisis. When President Kennedy was shot in 1963, Charles Coombs, of the New York Federal Reserve, was able to take immediate, decisive action to save the dollar, knowing he would be supported by his European counterparts. The same held true after the terrorist attacks on September 11, 2001. King recalled, "We can say things to each other, knowing they won't be leaked. You can do things without going through all the formalities. After 9/11, Alan Greenspan was out of the United States, and Roger Ferguson was in charge of the Federal Reserve. He and I were able to negotiate a swap agreement to supply liquidity in dollars for banks that needed them but could not get them at the Fed. The fact we could do that personally because we trusted each other enabled us to give confidence to our banks that they would be able to get dollars. That is a good example of where an informal connection can make a connection in practice, and that cannot happen unless you have had a long period of personal contact and interaction.

"Normally in that sort of situation, without that personal trust you would have to wait until all the legal details had been sorted out before you can tell someone it can go ahead, by which time it would be too late. Our ability to step in and say, 'Don't worry—it's going to be all right,' was very important."

The governors' weekends are a kind of sanctuary, says Nathan Sheets, who served as head of the Federal Reserve's division of International Finance from 2008–2011. "You are there with like-minded people, and there really is a sense of central bankers' brotherhood. At many other international meetings there is a sense of 'You Americans are doing this' and 'You Europeans are doing that.' At the BIS, the questions are what kind of challenges do we face? And how can we solve these together? Those relationships make it easy to pick up the telephone and call counterparts abroad. The governors know each other, they like each other and they know how each other think, thanks to these meetings."[26]

The BIS gatherings can bring constructive criticism, said Peter Akos Bod, a former governor of the National Bank of Hungary. "If something happened in your country, and you did or did not do something, the others raised questions. You had to face some friendly criticism if your inflation was out of line. The Bundesbank president, for example, would say, this measure that you have taken, why didn't you do that instead? And you would go home, and ask your staff, 'Why didn't we do that?'"[27]

The influence of the BIS is indirect but real, said a former central banker. "You hear things, they stick in your head, you come home, and you use them. Central banking is a very special business because you don't have competitors. If you are a car producer and you meet another car producer, you hide your cars. If you meet another central banker, you ask questions because you have a hell of a lot to learn, and he has

no reason to hide from you. From that point of view, these discussions are extremely useful."[28]

The governors' sense of common interest and their mutual trust has proved especially important during the crisis. King said, "We have adopted different forms of communication with the markets, and learned from the experience of others about what worked and what didn't work. The BIS meetings have helped us to formulate views about what we should do, and about the financial instruments we use. All the governors feel they benefit from sharing experiences, which is different from just getting documents."

Nonetheless, the governors' meetings are still dominated by a tight-knit, inner-core of the governors of the Federal Reserve, the ECB, and the Bank of England, who share decades-old connections. Ben Bernanke, Mario Draghi, and Sir Mervyn King all spent time at the Massachusetts Institute of Technology economics department. Bernanke and Draghi earned their PhDs there, while King taught there for a short time in the 1980s and shared an office with Bernanke.[29] The emphasis on status and hierarchy adds to the mystique of the BIS, said Pennant-Rea. "When you strip down the membership, only a relatively small number really matter. The United States above all, Germany and Britain to a minor extent. There is a very strong sense of pecking order."

But like all self-referential groups that rely on each other for mutual advice and reinforcement, the central bankers, cocooned in luxury and discretion at the BIS, can easily forget that they are public servants, said Andrew Hilton, the director of the Centre for the Study of Financial Innovation, a think-tank based in London. "It's a tricky one because you don't want them to be affected by day-to-day populist pressures. On the other hand, you do want them to know how much a pint of milk costs. The fine line you have to draw is between not being pressured by what's happening on the street, but also being aware of it. It's all too easy as a central banker to float over the political economy and throw bread to the masses. Central bankers should probably never be allowed to go anywhere in a limousine. They should take the Basel tram."[30]

Those central bankers who implement austerity programs do not personally suffer the consequences. Jean-Claude Trichet served as president of the ECB from 2003 to 2011. Europe's economies have slid into recession in part because of the ECB's relentless demands to keep inflation below 2 percent. Despite his role in the unfolding Eurozone crisis, Trichet is now a much sought-after speaker on the international conference circuit.

In May 2012 Trichet spoke at the Peterson Institute for International Economics in Washington, DC, offering his thoughts on the "Lessons from the Crisis." To an outsider the scene seemed an extraordinary spectacle: as Spain's economy began to collapse, neo-Nazis patrolled the streets of Athens, beating immigrants, and an entire generation of young Europeans faced years of unemployment and poverty. Trichet, however, was garlanded with praise and lauded for his insight. The French banker, said Peter G. Peterson, "played a decisive role in the Europe crisis as president of the European Central Bank until he stepped down last fall," which was indeed true, although not in the sense that Peterson intended.

The solution to the Eurozone crisis, argued Trichet, was not less supranationalism and technocratic rule, but much more. Trichet called for what he described as "a quantum leap" of economic governance, to accelerate the next stage of European integration. If a Eurozone member refused to obey instructions "coming from the center"—meaning European authorities—there should be the "activation of a federal government by exception." This policy, which even Trichet admitted would be at the "very, very, limit" of what would be acceptable, would mean that if "Your parliament is not behaving properly, we fine the country."[31]

Apparently oblivious to Europe's growing backlash against rule by technocrats, Trichet will have plenty of time to further hone his ideas for the end of national sovereignty in his new position as chairman of Bruegel, one of the foremost think tanks on European economic integration. The first president of the

ECB retired having wreaked "the sort of destruction on the European economy that hostile powers could only dream about," said Dean Baker, of the Centre for Economic and Policy Research, a liberal think tank. Trichet embodies the type of central banker who sees the economic crisis as something quite distinct from their responsibilities, said Baker. "Their job is to get inflation down, to 2 percent. The economic crisis is something bad that happened. It would have been nice if it did not happen, but it was not their responsibility, you cannot hold them accountable for it, and they don't have the tools to deal with it."[32]

Central bankers strongly reject this argument. Inflation, they say, is not a tap to be turned on and off when governments like to stimulate growth. "This is not something that you toy with," said one former central banker. "It is very easy for politicians to basically rob people of their savings by creating inflation. It is immoral, and anyway capital is much more mobile than it was ten or thirty years ago. The money will say you are creating inflation, goodbye, we are going to China or wherever, in a few seconds. It is much cleaner if we deal with the problem head on and do the painful things."[33]

Or as Stephen Cecchetti, the head of the BIS Monetary and Economic department, said, high debt levels are a "drag on growth." There can be no growth without structural repair and a gradual but credible reduction in debt levels. "As we have learned from years of experience with crises in both emerging market and advanced economies, the choice between austerity and growth is a false one. The true choice is between austerity and collapse. And that really is no choice at all."[34]

But the BIS's view is outdated. There is a choice, as even the IMF now argues.

> *"And they said, 'Come, let us build a city, and a tower with its top in the heavens, and let us make a name for ourselves, lest we be dispersed across the whole earth.'"* [1]
>
> — Genesis 11.3, The Tower of Babel

The story of the Tower of Babel is often read as a parable of the price of arrogance. Its builders started to construct the tallest building in the world, one that would reach to the very heavens as a physical manifestation of their greatness and ambition. Things ended badly.

The BIS tower, at Centralbahnplatz 2, in Basel does not reach to the heavens, but many of those working inside believe themselves possessed of a near-celestial mandate. Now seventy-three years old, the bank has evolved into one of the world's richest and most influential anachronisms. Montagu Norman's "cozy club" has sixty members. They circle the globe, from Colombia to the Philippines, Iceland to the United Arab Emirates, although the developing world remains underrepresented. The BIS employs around six hundred staff from more than fifty countries. Thousands of central bankers and their officials flock every year to the bank's numerous committees, meetings, and conferences.

Since 2007 the ongoing financial crisis has neither reduced the value of the BIS's assets nor dented its profits and prestige. The bank makes much of its money from the fees and commissions that it charges central banks for its services, such as short-term liquidity and credit, gold swaps, and by providing a range of investment opportunities and instruments. The BIS is a much sought after commercial partner. Its record is solid and conservative, its credit rating superb. In Basel at least, the crisis has, overall, been good for business. For the financial year ending in March 2009 the bank made net, tax-free, profits of 446.1 million Special Drawing Rights, the equivalent of around $650 million.[2] Its total equity was valued at the equivalent of almost $20 billion.[3] By the end of March 2012, profits had nearly doubled, to the equivalent of around $1.17 billion—almost $100 million a month—and the bank's total equity had increased by 40 percent to around $28 billion.[4] These are extraordinary sums for a single financial institution with just 140 clients and two local offices, in Mexico City and Hong Kong.

Even at a time when the IMF, not usually an advocate of generous public spending, has warned publicly and repeatedly against excessive austerity, at the BIS the legacy of Hjalmar Schacht, Montagu Norman, and Per Jacobssen endures.[5] The bank's managers regularly warn against the dangers of excessive lending and inflation. Austerity is seen as a necessary medicine, no matter how unpleasant its consequences. Such warnings are listened to.

The bank's influence is profound: the BIS is one of the world's most effective instruments of soft power. The bimonthly governors' meeting gathers central bankers from countries that control more than four-fifths of the world's GDP. The discussions at the Basel weekends have shaped the debate about the global financial crisis and the world's response to it. The committees hosted at the BIS are rebuilding the world's financial architecture and coordinating regulatory and supervisory policies. The Basel Committee on Banking Supervision oversees the capital requirement of commercial banks. Its work, wrote Ezra Klein, a columnist for the *Washington Post*, "will shape the future of global finance, and, by extension, the economy." Klein awarded the committee the title of the "Most Obscure-Yet-Important Regulatory Agency of the Year," noting, "its actions may only rarely make the front pages, but the work

done in Basel is crucial to creating a more stable world economy."[6] "Obscure yet important" surely brought knowing looks and quiet smiles at the BIS headquarters.

The bank's annual reports are regarded as essential reading in the world's treasuries and governments. The head of the bank's Monetary and Economic Department, who writes and oversees the annual reports, is one of the world's best read and most influential financial and economic analysts and commentators. The BIS hosts one of the world's largest restricted databases of banking information. Its mainframe computers sweep up data about the flow of transnational finance, including money flows in and out of offshore domiciles. Such information is of great interest to governments. Three months after 9/11 the Basel Committee on Banking Supervision hosted a meeting to coordinate central banks' and regulatory authorities' strategies on the prevention of terrorist financing and the sharing of records to prevent terrorist financing.[7]

The Financial Stability Board, hosted at the BIS, is likely to become the fourth pillar of the global financial system, after the BIS itself, the IMF, and the World Bank. The FSB coordinates national financial authorities and regulators. Its members include the Federal Reserve, the ECB, the Bank of England, and the national banks of China, Saudi Arabia, Switzerland, Russia, Japan, and Korea. The IMF, the World Bank, the European Commission, and the BIS itself are also members of the FSB, as are three of the most powerful committees hosted at the BIS: the Basel Committee on Banking Supervision, the Committee on the Global Financial System, and the committee dealing with payment and settlement systems. The writer Matt Taibbi once memorably described Goldman Sachs, the giant investment bank, as a "vampire squid."[8] The BIS is now the vampire squid of the regulatory world, hosting a myriad of committees that in turn spawn a raft of subcommittees, many of which are composed of the same central bankers and officials, each producing reams of reports that are passed back and forth from Basel to national central banks and governments in an endless merry-go-round of resolutions and recommendations.

Others argue that the answer to the banking crisis is not more insider committees and regulatory bodies hosted at the BIS, or anywhere else, but much less, or none at all. "Banking should become a normal industry, like manufacturing bicycles," said Andrew Hilton, of the Centre for the Study of Financial Innovation. "Banking should be regulated to protect against fraud, to protect consumers, and to protect the banks' integrity, but nothing else. That sounds crazy because everyone says that banking is special. Banking is only special because the sums of money flowing through these institutions are so large they can bring society down. If the banks were smaller, if they did simpler things and they were not a systemic threat, either individually or within a cluster, you would not have to regulate them. The banks would take out insurance and the system would be protected."[9]

Such views are regarded with horror in Basel. Yet, the heart of the matter is that BIS is an opaque, elitist, and anti-democratic institution, out of step with the twenty-first century. The BIS should have been closed down in the early 1930s, after the collapse of the German reparations program. Instead it funded the Holocaust and the Nazi war machine. Its staff members, such as Thomas McKittrick and Per Jacobssen, passed vital economic intelligence to the Nazis—often with the knowledge of the Allied authorities. The bank embodied the most cynical kind of capitalism. While millions died, it kept financial channels open across the frontlines.

After 1945 the BIS and its allied committees shaped much of the postwar financial world. Behind the scenes the BIS provided the necessary financial mechanisms, support, and technical expertise for the financial aspects of the Euro-integrationist project. Without the BIS the euro would not exist. The BIS gave birth to the European Central Bank, a bank that is accountable neither to the European Parliament nor to any government, even though it controls the monetary policy of seventeen countries. The BIS has

survived through the decades just as it was born—by opacity, secrecy, and by hiding behind a carapace of legal immunities. These protections perpetuate the technocrats' belief that a tiny, self-selecting elite, unaccountable to everyday citizens, should manage global finance. The BIS's privileges are a hangover from a thankfully vanished age of deference to authority, at least in the developed world.

Andrew Crockett, the bank's general manager from 1994 to 2003, did peel back some of the bank's obsessive secrecy. When the BIS was drawn into the torrent of revelations about Swiss banks, looted gold, and collaboration with the Nazis that erupted in 1996–1997, Crockett opened up the bank's wartime archives. It was a sensible decision and a boon for historians and investigators. "Our view was that if anyone had done anything bad it was a long time ago, so there was nothing in it for us to hide it. We decided that the only answer was complete transparency," recalled William White.[10] The bank spent two hundred thousand Swiss francs on specialized computers to digitize and microfilm the records, which had been neglected for decades, and hired a specialist historian, Piet Clement. (Crockett also made himself available for interview on the BIS's wartime record and spoke at length to the author, which is included in the author's 1998 work *Hitler's Secret Bankers: The Myth of Swiss Neutrality During the Holocaust*.) The bank's archives, which are open under the thirty-year rule, are a valuable resource for historians.

But the BIS is far less forthcoming about its present-day governance. The bank's annual reports and other documents are available on its website, and it has a Twitter feed: @bis_org. In February 2013, it had more than thirteen thousand followers. The bank often tweets several times a day, with links to speeches by central bankers as well as studies and working papers published by the bank, thus providing a continuous update to the documents available on the bank's website. But this information is already in the public domain. Information about the bank's internal operations, such as the agenda and themes of the governors' meetings, the elite Economic Consultative Committee, or the attendance list, and the transactions the BIS carries out with the public funds held by central banks whose reserves it manages are not tweeted and nor, at least for the foreseeable future, are they ever likely to be. Rather, the emphasis remains firmly on confidentiality. When the author asked Stephen Cecchetti, the bank's economic adviser, about the high level of secrecy around the governors' meetings and the BIS's activities, he replied, "Banks have confidentiality agreements that bind them not to disclose information about their customers. In the conduct of its banking business, the BIS strives to exceed best practice in its customer relationships."[11]

There is usually no press conference or press statement after the governors' meetings, but the BIS has for years held a press conference after the Annual General Meeting and the release of the annual report. The 2011 gathering, which can be viewed online, was a low-key, even desultory affair.[12] Jaime Caruana, the general manager, read a prepared statement. He and Cecchetti then invited questions from the handful of journalists present. There were four questions: three about the work of the Basel Committee and one about monetary policy. Cecchetti did not speak. The press conference lasted seventeen minutes. The journalists were specialist correspondents. There was no press conference in 2012. The journalists covering the BIS told the bank it was not necessary as the bank releases the annual report with a long embargo and also organizes a teleconference. Had there been a press conference in 2012, a general reporter would have honed in on a much stronger story—one which raises profound questions about the bank's tradition of secrecy, its legal immunities and their implications for the bank's future.

IN 1991 ARGENTINA went bust and defaulted on almost $81 billion worth of debts. The Argentine government eventually offered creditors thirty-five cents on the dollar—previously bankrupt countries had offered fifty to sixty cents. Nonetheless, by 2010 93 percent of creditors had accepted the offer. The

remainder, however, were still holding out, demanding a higher payout for their $6 billion worth of debt, including accrued interest. The two main groups are around sixty thousand people in Italy, some of whom bought Argentine bonds to fund their retirement, and a pair of investment funds—Elliott Management and an affiliate, NML Capital—known as "vulture funds," which chase countries in default and which bought many of the bonds in secondary markets. Elliott has chased the Argentine central bank through the American courts. The Italian bondholders are fighting their case at the International Centre for Investment Disputes, which is part of the World Bank group. Both the funds and the Italian investors have won several legal victories.[13]

However, the Argentine central bank has shipped a substantial part of its reserves to the BIS, where the monies are out of the creditors' reach. The funds are now suing the BIS and drawing unwelcome attention to the bank's hyper-privileged legal immunities. The funds allege that the BIS has allowed the Argentine central bank to store between 80 and 90 percent of its $48 billion in foreign reserves in Basel (most central banks keep a small proportion of their reserves there). Lisa Weekes, the bank's head of press, declined to answer detailed questions from the author in December 2012 about the Argentine reserves but pointed to a letter she had published in the *Wall Street Journal* in July 2011.[14]

Weekes confirmed in that letter that the Argentine central bank holds an account at the BIS. The BIS will not disclose the actual sum deposited by the Argentine central bank, citing client confidentiality, but said that the figure of around $40 billion is "grossly overstated." The letter noted that the Swiss Federal Tribunal, Switzerland's highest court, rejected the funds' action and upheld the BIS's immunities, noting that "accepting central banks' deposits is part of the BIS's mission, enabling it to fulfill its statutory function as an international settlement hub for central banks." The BIS, wrote Weekes, like other international organizations, is "protected by immunities that that allow it to carry out its functions in the public interest."

The definition of "public interest," however, looks rather different to the holders of Argentine bonds. The Argentine BIS deposits are a "clear deviation of the bank's standards," wrote Claudio Loser, a former director of the Western Hemisphere Department of the IMF. "The BIS has a serious conflict of interest: it is playing the interests of one national depositor against the interests of many others."[15] In December 2012 the Swiss Federal Council (the Swiss federal government) confirmed that the funds cannot sequester any of the Argentine deposits held at the BIS. The council ruled that there had been no abuse of immunity of the 1987 headquarters agreement between the BIS and the Swiss Federal Council, which governs the bank's legal statues and immunities.

So for now, at least, the BIS seems to have won the battle over the Argentine reserves. But the wider questions remain. What if other countries seek to use the bank as a refuge from their creditors? "Argentina is a big question for the bank," says one former BIS official. "Is the government depositing with the BIS because it is a good place to put its money, or because its deposits are immune and the BIS cannot be sued and forced to surrender them?"[16] The BIS has also helped to repatriate looted money. After the death of the Nigerian dictator Sani Abacha in 1998, the Nigerian authorities pursued hundreds of millions of dollars that had been looted and deposited in Swiss banks. In 2004 the Swiss authorities ordered that almost $500 million be transferred from Swiss banks to a holding account at the BIS for Nigeria, before being transferred to the country's central bank.

The Argentine reserves and the Nigerian looted assets highlight how the BIS's immunities are a double-edged sword: they arguably provide safe haven for a country fleeing its creditors but also ensure that the BIS is the bank of choice for diplomatically sensitive transactions such as the return of looted assets. "It's very important that an institution that is mainly dealing with the central banks of sovereign countries should have full immunity in its financial transactions from the jurisdiction of national legal

systems, as do the IMF and World Bank," said Malcolm Knight.[17] Every country dealing with the BIS should be required to sign a single, consistent agreement similar to that required by the IMF, that would provide immunities for all the financial transactions of the BIS with residents of that country, as well as other immunities necessary for the operation of an official international institution, such as immunities for its staff while traveling, said the former BIS general manager.

The BIS "has not become a refuge in any sense at all," said King.

> *It's very important that in the future sovereign debt issues will not lead a sovereign debtor into a position where it can be exploited by a small minority of creditors who will not go along with the restructuring. The BIS is not special in this debate. This is a much broader debate about how we deal with sovereign debt restructuring. Should creditors such as vulture funds be able to buy their way into sovereign debt and then try and extract a position that is much more favorable to themselves than any other creditor? In the future, sovereign debt should be issued with "collective action clauses" to prevent such holding out behavior, but in a way that is part of the legal rules of the game. The BIS is no different to the IMF or any other international body that has a degree of legal exemption.*[18]

The bank's belief that it should be so rigorously protected embodies its central contradiction: that it is shaping the regulatory future of global finance and calls for good governance, yet its own affairs are kept firmly hidden behind a thicket of legal immunities and protections.

THE BIS PROGRESSES through the twentieth-first century with ever more confidence, even though there is no need for it to exist. Its banking services could be carried out by commercial banks, which would be legally bound to observe the necessary confidentiality to prevent market speculation on the central banks' interventions. Its research department and its databases could be relocated to any decent university. Its famed hospitality could be easily replicated in any number of luxury hotels or conference centers. The committees hosted by the BIS that regulate banking and the international financial system could be relocated to the IMF or housed in a new think tank, with open and transparent governance. Breaking down the bank into its constituent parts would help democratize global finance.

Yet the bank is not worried. It has powerful friends, who, it believes, will ensure its inviolability and survival. The Swiss Federal Council, the governing body of the country where the bank is based, has strongly re-affirmed its commitments to the BIS's legal inviolability. The board of directors, which manages the bank's affairs, reads like a who's who of the world's most powerful central bankers. It includes Ben Bernanke, Sir Mervyn King, Mark Carney, Mario Draghi, Jens Weidemann of the Bundesbank, and Zhou Xiaochuan of the Bank of China. The bank's management can reach any one of these with a telephone call, knowing that the governors will make time for them.

The bank's collective memory is reassuring too: in 1945, the BIS outmaneuvered powerful enemies, such as Henry Morgenthau, the US Treasury secretary who wanted the bank to be closed down for collaborating with the Nazis. Whatever legal or political travails may lie ahead, such as the breakup of the Eurozone, a deepening of the financial crisis, or even a new war, banking insiders say there will always be a need for a financial intermediary operating across the lines and behind the scenes.

The BIS helped give birth to the euro and will also be ready to step in should it fail. If the euro crisis worsens and the single currency breaks up, the BIS's expertise will be deemed essential to ensure that the fallout is contained. In early 2013, as this book went to press, there were signs that the Bundesbank,

which had been forced against its will to adopt the single currency, was now placing its faith in the oldest store of value of all: gold. The Bundesbank announced that it plans to repatriate 300 tons of the gold it holds in the vaults of the New York Federal Reserve. Germany stores more than two-thirds of its gold reserves, which are worth $183 billion, in New York, Paris, and London. All 374 tons will be removed from Paris, although the German holdings will stay in at the Bank of England.

The decision to move the gold out of Paris but leave it in London was immediately interpreted as a loss of faith in the euro and the supranational project. As the Eurozone and European superstate project totters, gold mania is sweeping through Germany. Humanity's favorite store of value is seen as a safer bet than a currency barely a decade old. In 2012 the German state auditing agency demanded that the Bundesbank carry out an inventory of all German gold stored abroad. Bundesbank officials said that they personally checked all the holdings, which were accounted for. The gold mania would seem very familiar to Hjalmar Schacht and Montagu Norman. Folk memories run deep, especially in Germany, which has twice faced economic meltdown in the last century—in 1918 and 1945. The much-vaunted German economic miracle was always rooted in massive injections of foreign capital, by Wall Street in the 1920s and by the United States government after 1945. Such largesse is unlikely to be repeated nowadays. If the euro collapses, gold is a safer bet than hoping for another transatlantic bailout.

The new emphasis on gold can only be good news for the BIS, and is a return to the bank's roots. As Gianni Toniolo, the author of the BIS official history, notes, the gold standard—fixing the value of a currency to a weight of gold—was "embedded in the very DNA" of the BIS.[19] The gold standard is long gone, but gold prices continue to rise, and gold still has a powerful hold over investors' psyches. It is certainly ever more central to the BIS's banking operations, so much so that the *Financial Times* has described the bank as "the ultimate bullion pawnbroker."[20] The BIS 2012 annual report revealed that the bank holds 355 metric tons of gold (worth almost $19 billion) in connection with its gold swap contracts, meaning that the bank exchanges currencies for gold, which it returns at the end of the contract.[21]

The BIS would be an essential part of any rescue operation if the euro fell apart, said Rudi Bogni, a veteran international banker. "The BIS could certainly help technically; it has the skills required for any intervention in the markets, should it be required." The BIS could also prove useful in darker scenarios, such a major new war. And it certainly has extensive experience of keeping financial channels open between warring parties. In the modern, globalized economy, preserving those links would be judged even more important than in the Second World War. "When people start shooting at each rather than talking to each other, the economies and trade still continue. There is always an interest that is bigger than war," said Bogni. "Even in death you have financial interests that continue after the death of the individual. So in a war where the parties are not dead, they will want to continue those interests after the war."[22] Basel would doubtless, once more, be the place of choice to keep those channels open.

Yet the second decade of the twenty-first century could yet turn out to be the most challenging, even perilous, for the bank. The bank has profited immeasurably from the rapid pace of globalization and economic development and will further do so as new members join from the developing world, all eager to profit from the BIS's expertise and banking services. "There are many emerging market economies for whom the BIS banking operations have real value," said King. "They would feel they would lose something without a bank for central banks."[23]

But the ongoing financial crisis has changed more than banks' balance sheets. Citizens and activists around the world are demanding accountability and transparency from banks and financial institutions. Yet, most have never heard of the BIS, an information deficit that this book has hopefully filled. The bank's management views the BIS's legal inviolability, which is protected—like that of the United Nations and the European Central Bank—by international treaties, as its greatest strength and believes the

BIS to be protected in perpetuity. Yet the bank's statutes, written in 1930 for another age, of deference and obedience, may turn out to be its Achilles heel.

The question of the Argentinian reserves raises profound questions about the BIS's legal inviolability. The BIS's immunities could soon be tested again. By early 2013 most observers expected Greece to renegotiate its sovereign debt, which would demand that investors holding Greek bonds would have to take a "haircut" and write off some of the value of their holdings. What would happen, then, if Greece, like Argentina, shifted its foreign reserves to the BIS to avoid angry creditors? If Greece followed Argentina, perceptions of the bank will shift. The BIS's claims of moral probity and of acting in the "public interest" will start to appear decidedly shoddy. For now, the bank has the protection and support of the Swiss courts and the Federal Council. But even in the land of the anonymous, numbered account, public—and legal—opinion is shifting about the country's reputation as a refuge for those seeking legal inviolability. Switzerland is under sustained pressure from the US and European authorities to ease its secrecy and guarantees of anonymity.

As long as Argentine foreign reserves remain out of the creditors' reach, the BIS sets a unsettling precedent: that if a BIS member country defaults, or is about to, it could ship its national reserves to Basel for safekeeping. There are the beginnings here of uncomfortable—for the BIS—parallels with the 1930s and '40s. In March 1939 Montagu Norman, one of the bank's founders and most powerful directors, and Johan Beyen, the BIS's president, refused to stop an order from the National Bank of Czechoslovakia to transfer some of its gold holdings from its BIS subaccount at the Bank of England to the Reichsbank BIS subaccount. It was obvious that the transfer order, given after the Nazis had invaded Czechoslovakia, had been issued under duress. Yet Norman deliberately took the view that the interests of the BIS and the new, transnational financial system were more important than refusing, or even delaying the request. Beyen went along with this decision. The gold was credited to the Reichsbank's account. During the Second World War years, the bank acted as a depositary for looted Nazi gold, even though Thomas McKittrick, the president, was specifically warned that the gold might be stolen. He believed that the bank had no business asking where the gold came from and was anyway protected by its statutes. But even with its powerful allies, the bank still had to fight hard to escape being closed down because of its acceptance of looted gold.

For now, the BIS's statutes and the support of the Swiss legal system ensure that its reserves are untouchable. But laws—and treaties founding international banks—are made in a political context and can be changed. Legal and political pressure could mount. The change in perception of the bank is already happening. Influential analysts and economists, such as Claudio Loser, cited above, are questioning the bank's ethics, behavior, and legal inviolability. In the age of Twitter and Facebook, the BIS, once its central role and importance is known, could yet find itself at the center of a global firestorm.

The BIS's assets may remain untouchable, but as more activists understand the bank's role in the global financial system, its secrecy and elitism, they will increasingly question its operations, role, and need to exist. Such a shift in global perception of the BIS, and the demands to make it more accountable, will bring pressure on politicians, which will then be passed on to the central bank governors, who are independent but still appointed by governments. The controversy over the Argentine reserves could, in turn, corrode the basis of the bank's soft power: its regulation and supervisory frameworks. Commercial banks, might, for example, ask why they should adhere to the Basel Committee's banking rules, when the host bank itself is arguably protecting a central bank against its creditors?

For now, at least, the BIS can rely on its powerful friends. But if the political climate continues shifting toward transparency and accountability, the bank's managers may find that their calls take longer to be returned and are briefer in duration. The bank needs to reform in three areas to ensure its survival:

transparency, accountability, and corporate social responsibility.

The first is the simplest. The BIS should hold a press conference after the bimonthly governors' weekends and make it available on the Internet. The bank should publish the attendance list and the broad themes of discussion at the weekend meetings, in particular of the elite Economic Consultative Committee that meets for dinner on Sunday evenings; the Global Economy Meeting the next day, the BIS directors' meeting that deals with the bank's governance, and deliberations of the Markets Committee, which deals with the international financial markets.

The BIS and the central bankers argue that such a move would inhibit discussion. King said,

> *The BIS has moved quite a long way to being open about the state of its finances, its legal position, its board membership, and how it works. The membership of the BIS is well known, and from that you can infer that the governors of the member countries will come to the meetings. The themes and subjects of discussion are of value solely because they are confidential. I would contrast the BIS meetings with the G20 and the IMF where communiqués are published, which purport to be transparent and report what is said. But the expectation of publication constrains useful discussion.*
>
> *The whole point of the BIS conversations is that they are private and are confidential. There has to be a role for private conversations for them to be useful. You cannot have every conversation between central bank governors being minuted and reported. Then there are no useful conversations, simply people making public statements at each other.*
>
> *We don't do deals at Basel. It is too strong to say that this is coordination or harmonization as responsibility, for policy making remains with national central bank committees. The BIS meetings do make us much better informed about why people have done various things and maybe what they intend to do in the future.*[24]

It is true that central bankers do need to be able to speak freely to one another. But there is no need to put a camera in the room and post the video on YouTube or even release a transcript. But the bank should publish minutes: the broad themes of discussion, the lines of debate, and the overall conclusions of the meetings. All the central bankers and officials present at the governors' meetings are public servants, charged with managing national reserves, which are public money. The central bankers are accountable to the citizens who pay their salaries and pensions. It is no longer acceptable for them to gather in a secretive cabal and refuse to release even minimal details of their meetings. The US Federal Reserve is a useful model here. Before each meeting of the Federal Open Markets Committee, the bank releases edited minutes of the previous meeting. The Federal Reserve's website already carries detailed information about which bank officials are attending the BIS weekends and their hour by hour itinerary while in Basel. Neither the Federal Reserve nor the dollar nor even the BIS have collapsed as a result.

Central bankers argue that the comparison is not valid as the BIS is not a decision-making body. King said, "We publish minutes at the Bank of England because we take a formal decision that we have been mandated to take by the UK government. There are no formal decisions like that taken at the BIS. If the BIS was taking interest rate decisions, it would be right to have that degree of transparency. We don't generate decisions at the BIS. We have informal discussions, then we go home and we take our decisions."[25]

Secondly, the BIS should be stripped of its legal inviolability. The BIS is a bizarre hybrid—an extremely profitable commercial banking operation protected by international treaty. Its founding statutes

are certainly out of step with the modern age. The statutes provide unnecessary levels of legal protection for a bank dealing in public funds, and they warp the psychology of the BIS. They fuel the peculiar arrogance of much of its senior management. The bank claims to have a mission of public service, yet is structured in such a way that the public is kept as distant as possible, behind the bank's wall of legal immunities. Such a change would demand an Extraordinary General Meeting (EGM). There is a precedent here. In recent years, EGMs were called to change the bank's unit of account from the gold franc to the Special Drawing Right, to forcibly buy back the shares held in private hands, and to distribute the shares held by the former Yugoslavia to its successor states. Voting is decided at EGMs by member central banks. If the governors and officials of the member central banks were mandated by their national governments to vote for the change and modernization, the bank would have to accede to the changes.

Thirdly, such an EGM could also mandate the bank to spend some of its profits on corporate social responsibility and philanthropy. The bank has for decades reaped rich rewards of its stewardship of public funds. In the financial year 2011–2012 the BIS made tax-free profits of almost $100 million each month. It is time to return some of those profits to a wider society, beyond the annual dividends paid to the central bank shareholders. The bank refused to answer questions from the author on how much it spends on charity and philanthropic projects. The words "philanthropy" and "charity" do not appear in the 2011–2012 annual report. Lisa Weekes, the bank's head of press, said that as most of the bank's staff live in or near Basel, the BIS provides "modest financial support for selected initiatives or institutions within the Basel region . . . with a social or cultural purpose."[26] The bank also makes ad hoc donations in response to major natural disasters, such as for the typhoon victims in the Philippines in December 2012, but refuses to say how much.

This is feeble. It is time for the BIS's much-vaunted globalism to extend to its social conscience. The bank should set up a charitable foundation—George Soros's Open Society Institute could be one model—to support global training, education, internship, and development programs for young business people and bankers. One day's worth of annual profit—$3.2 million—would be enough to kick-start such a program, which with the BIS's imprimatur would soon attract corporate sponsorship. The bank's staff could be encouraged to contribute, in lieu of the income tax they are spared. The foundation should be given a block of shares to ensure that civil society has a vote at the bank's annual general meeting. A group of real people at the meeting, outside the charmed circle of the central bankers and their officials, would provide a useful and refreshing reminder that the central bankers' policies and decisions, and those of the BIS, have consequences in the outside world.

Central bankers counter that the BIS already gives something back to society through its numerous seminars and meetings, and by hosting the Financial Stability Institute, which was set up by the BIS and the Basel Committee on Banking Supervision in 1999 to work with financial sector supervisors. King said,

> *They do a lot of good work in providing opportunities for smaller members of the BIS to come and learn. There is an informal workshop about governance and the challenges of running a central bank, and smaller members of the BIS have found this of immense value. They belong to a club where they have a chance to quiz their central bank colleagues. At home there was no one to ask for advice. That kind of exchange is invaluable. That is the BIS using the resources of bigger countries to put something back into emerging markets and developing countries.*[27]

There are small but encouraging signs that some central bankers understand that with great financial power comes social responsibility. In October 2012, Andrew Haldane, executive director for financial stability at the Bank of England, gave a speech on "Socially Useful Banking" at a meeting hosted by Occupy Economics, the London branch of the social protest movement.[28] The Occupy movement, he said, had helped trigger the first stages of a "reformation of finance." Policymakers were listening to criticism and were acting to close the "fault lines" in the global financial system. "Occupy has been successful in its efforts to popularize the problems of the global financial system for one very simple reason: they are right." Over the years, there had been a "great sucking sound" as "people and monies" were drawn into banking, especially investment banking, draining human and financial resources from the rest of the economy. Even the BIS agrees. Haldane quoted recent research by the bank, which found that when the financial sector reaches a certain level it impedes growth because the financial sector competes with other parts of the economy for scarce resources. "More finance is definitely not always better," wrote Stephen Cecchetti and Enisse Kharroubi.[29]

WHAT THEN DOES the future hold for the BIS? Over the decades, from the Schacht-Norman era, through the Second World War and the birth of the euro, to the present-day jamboree of regulatory committees, the bank has demonstrated an extraordinary ability to make itself essential to the times, repeatedly jettisoning its historical baggage and re-inventing itself to preserve its central place at the heart of the global financial system.

Keenly aware of the growing global hostility toward bankers, the BIS now emphasizes its status as an international organization and its contribution to the common good. This is certainly an effective recruiting tool. "The quality of the people working at the BIS is very high," said King. "It helps, when recruiting really good individuals, to say this is an international institution for which you work, not just a think tank. People like to feel they are working in public service."[30]

But the bank's latest evolution, into a socially responsible institution, may prove the most difficult. Secrecy, opacity, and unaccountability—like gold—are embedded in the bank's DNA. The bank will find it difficult to adjust to the new demands, outlined by Andrew Haldane, that financial institutions be accountable and socially responsible. Yet to survive, it will have to. In an age when information flows as fast as capital, when citizens demand ever more transparency and accountability from the institutions that have power over their lives, when even Wall Street can be occupied for weeks, the Tower of Basel is no longer inviolable.

Unlike its biblical predecessor, the Tower of Basel reaches only eighteen stories above the city skyline. But the fate of the biblical tower-builders should give the bankers pause. For when God saw their work, he confounded their speech and introduced a multitude of tongues. The builders could no longer understand one another. The construction work stopped, they were dispersed, and their tower vanished into history.

Acknowledgments

This book was born out of a conversation in New York with Clive Priddle, the publisher of PublicAffairs. Clive has been the best editor a writer could hope for: encouraging, insightful, and deeply knowledgeable. My brilliant agent, Elizabeth Sheinkman, of William Morris Endeavor, was an enthusiastic advocate of this project, and Jo Rodgers was always there to help. Numerous friends and colleagues provided encouragement, advice, and ideas, especially Roger Boyes, Justin Leighton, Erik D'Amato, and Nicholas Kabcenell. In New York, Peter Green, Bob Green and Babette Audant were warm and welcoming hosts, while Matt and Emmanuelle Welch in Washington, DC, provided a home from home. In Budapest, I am especially grateful to Flora Hevesi, who diligently transcribed many hours of interviews and never once complained about technical and banking terms. Many thanks to Lori Hobkirk for her production, organization, and editing expertise, to Daisy Bauer for her elegant design, and to Beth Fraser for her diligent copyediting.

Tower of Basel is a book about networks, connections, and the exercise of covert power. Mapping those links is always easier when insiders and former insiders are ready to share their expertise and knowledge. I spoke to numerous sources with firsthand knowledge of the Bank for International Settlements, the world of central banking and related themes. Some prefer to remain anonymous; they know who they are and I am very grateful for their insight. Others did agree to speak on the record. My thanks to Dan Alamariu, Peter Akos Bod, Dean Baker, Geoffrey Bell, Rudi Bogni, Stephen Cecchetti, William de Gelsey, Charles de Vaulx, Adam Gilbert, Richard Hall, Frigyes Hárshegyi, Andrew Hilton, Zsigmond Járai, Karen Johnson, Sir Mervyn King, Malcolm Knight, William McDonough, Laurence Meyer, Ron Paul, Rupert Pennant-Rea, Nathan Sheets, Paul Volcker, and Peregrine Worsthorne. William White was especially informative and helpful. Thanks also to Sarah Ashley at the Bank of London press office, Gillian Tett, Ralph Atkins, David Dederick, Paul Elston, Barbara Wyllie, Steve Bloomfield at *Monocle*, Jonathan Brandt, John Hubbel Weiss, Peter Grose, John Lloyd, Greg Ip, Peter Rona, William Clothier at Brody House in Budapest, Paulina Bren, Zoltan Markus, Mark Milstein at Northfoto, Alex Kuli, and the folks at the Federal Reserve Press Office. Ryan Avent read the manuscript and shared his insight into the world of central banks while John Shattuck kindly gave me access to the Central European University's library in Budapest. Lee Goddard built me a fine website at www.adamlebor.com.

I am especially grateful to the staff of the following archives: Bank of England; Columbia University Rare Book and Manuscript Library; Federal Reserve Bank of New York; Franklin D. Roosevelt Presidential Library; Seeley G. Mudd Manuscript Library at Princeton University; National Archives, London, and the US National Archives and Records Administration at College Park, Maryland. Special thanks go to my team of researchers. In London, Rosie Whitehouse found valuable material in the Bank of England archives. Elysia Glover diligently searched the records of the Federal Reserve Bank of New York, the archives at Columbia University Library and the Henry Morgenthau diaries, which are held at the Franklin D. Roosevelt Presidential Library in Hyde Park. In Washington, DC, Emmanuelle Welch at French Connection Research (www.frenchpi.com), located a number of valuable documents at the US National Archives. Andras Lengyel and Esther Judah deftly translated from German and French into English.

This book is an unauthorised investigative history of the BIS and has not been read or vetted by any staff member or bank official. However I would like to extend my thanks to several people at the BIS.

Edward Atkinson was always insightful, and good-humored as he guided me through the archives. Dr. Piet Clement, the bank's historian, readily shared his knowledge of historical matters, no matter how arcane. Margaret Critchlow and Lisa Weekes at the BIS press office kindly added me to the bank's media mailing list, answered a good number of my questions, provided numerous photographs, and arranged an interview with Stephen Cecchetti, the head of the Monetary and Economic Department.

All works of historical enquiry draw on their predecessors. I am glad to acknowledge the contribution of Professor Gianni Toniolo and Dr. Piet Clement. Their authoritative study of the BIS, *Central Bank Cooperation at the Bank for International Settlements 1930–1973*, is an invaluable work of reference. I am especially grateful to Christopher Simpson, professor of journalism at American University, and to Jason Weixelbaum, a very talented, young historian. Professor Simpson, a pioneer in researching the connection between big business and genocide, was extraordinarily generous with his time and expertise, guiding me through the US National Archives and sharing original documentary material from his own archive. Jason Weixelbaum, an expert in the links between American companies and the Nazis, shared a number of documents about the BIS and allied themes and was also a tenacious researcher. Professor Harold James was generous with his insight into the BIS and the historical backdrop to this book. Donald MacLaren kindly shared his insight into his father's life and work. I am grateful to Helen Scholfield who first contacted me about the extraordinary story of how British secret agents worked against Nazi economic interests in the United States. That episode, like much wartime cross-border economic intrigue, leads back to the BIS.

Thanks most of all to Kati, Danny, and Hannah, for putting up with my long absences, and for daily reminding me that there is indeed life outside the *Tower of Basel*.

21. Currently, there are no figures available for the total amount of foreign exchange bought and sold by the BIS to its various counterparties, including the Reichsbank, during the war years. The information is available in the BIS archives in the files dealing with BIS- Reichsbank transactions, and the BIS's foreign exchange records, but has not been compiled. Most of the transactions involve the Reichsbank, selling Swiss francs to the BIS to cover the interest payments on the bank's investments in Germany. These transactions were usually in the range of 200,000 to 300,000 Swiss Francs, but they ended in January 1943 when the Reichsbank began paying its obligations to the BIS in looted gold. The author is grateful to Piet Clements, the BIS historian, for this information.

25. Rudy Kennedy survived in Auschwitz for almost two years. In January 1945 he was moved to Dora-Mittelbau where V-1 and V-2 rockets were manufactured by Werner von Braun, the Nazi rocket scientist whom Allen Dulles later brought to the United States. Kennedy was then sent to Belsen where he was liberated by British troops in April 1945. After the war he settled in Britain and became a successful businessman and campaigner for justice for former slave laborers. Kennedy fought tirelessly for decades against IG Farben, its successor companies, and the German government, demanding that the company accept liability and pay adequate compensation. Under great pressure from the State Department, organizations representing slave laborers eventually signed an agreement in 2000 that paid around $7,000 to each victim. IG Farben's successor companies contributed to the settlement. Those accepting the offer were forced to surrender any future claims. Kennedy refused to sign and carried on campaigning. He died in 2008 at the age of eighty-one.

26. See R. Billstein, *Working for the Enemy: Ford, General Motors and Forced Labor in Germany During the Second World War* (New York: Berghahn Books, 2000). In the late 1990s Ford opened its archives and commissioned archivists and historians to scrutinize its wartime record. Their findings are compiled in a 208-page report, published in 2001. "Research Findings About Ford-Werke Under the Nazi Regime," is available at http://media.ford.com/article_display.cfm?article_id=10379. The report also notes that Ford and its subsidiaries in Allied countries made a crucial contribution to the Allied war effort, producing vast amounts of aircraft, military vehicles, engines, generators, tanks, and military ordinance.

27. Michael Dobbs, "Ford and GM Scrutinized for Alleged Nazi Collaboration," *Washington Post*, Nov 30, 1998. At this time General Motors opened its archives to the historian Henry Ashby Turner Jr., the author of *German Big Business and the Rise of Hitler*, which downplayed the role of the industrialists in supporting the Nazis. In 2005 Turner published *General Motors and the Nazis: The*

Struggle for Control of Opel, Europe's Biggest Carmaker . The book argued that by 1939 General Motors had lost control of its German subsidiary and so had no power over Opel's military production or use of slave labor. This view is not universally accepted.

41. Ibid. In December 1998 lawyers acting on behalf of Holocaust victims and their families filed a class action lawsuit in New York against Chase Manhattan bank, J. P. Morgan, and seven French banks, alleging that the US banks' French subsidiaries were complicit in the seizure of the wealth of French Jews who were deported to concentration camps. Chase Manhattan said the suit was "unnecessary" as it was working with Jewish organizations to examine its historical records to identify former customers or their heirs, and pay the customers, or their heirs, with interest. J. P. Morgan soon agreed to settle for $2.75 million. Much of this remained unclaimed and those monies were donated in 2003 to Yeshiva University in New York to endow a center for Holocaust studies. J. P. Morgan and Chase Manhattan merged in 2002 to become J. P. Morgan, Chase & Co. The claims against Chase Manhattan were dealt with by the Drai Commission, a French government organization, which oversaw restitution claims against French banks. The class action lawsuit was one of several targeting American, Swiss, British, and other European banks over their wartime records. Swiss banks eventually agreed to pay restitution of around $1.25 billion. Barclays Bank, in Britain, agreed to pay out $3.6 million to compensate families who had lost assets in France during the Nazi occupation. See: Michael J. Bazyler, *Holocaust Justice: The Battle for Restitution in America's Courts* (New York: New York University Press, 2005).

FOREWORD

We think we're number one, but we'll leave that for others to decide." Back in 1983, when John Whitehead, then cochairman of Goldman Sachs & Co. made that statement to a reporter from New York magazine, the investment bank was already well on the way to becoming one of Wall Street's iconic firms. Its bankers proclaimed that they were "long-term greedy"; the denizens of Goldman weren't the type, they declared regally, to try to capture every fraction of a penny of fees and profits, particularly if there was even a question that they might be doing so at the expense of a client relationship. Goldman Sachs even felt itself to be above some businesses—no advising hostile bidders on takeover strategies, for instance; that was far too messy. Then there were some potential clients that a Goldman Sachs banker didn't want to be seen lunching with, much less transacting business with. Goldman's clients were the crème de la crème; preserving the firm's name and reputation by choosing who to deal with and what deals to do was more critical than grabbing at an extra few thousand dollars in fees.

Occasionally, something unpleasant would happen to remind Goldman bankers of the solid business reasons behind those lofty principles, such as the firm's brief but damaging relationship with Robert Maxwell. Many Goldman partners had felt skittish about accepting the media tycoon as a client; his checkered past included his being dubbed by a British government inquiry as "not a person who can be relied on to exercise proper stewardship" of a public company. But the allure of earning big fees overrode those concerns —that is, until Maxwell vanished off his yacht into the sea near the Canary Islands and a new investigation revealed that he had looted a billion pounds from his employees' pension funds. British regulators hit Goldman with a fine for its role in the fiasco in 1993; the size of the fine was somewhat less important than the public humiliation, however. Partners vowed that never again would Goldman Sachs be named and shamed in such a manner.

And yet, in the summer of 2010, Robert Khuzami, head of the enforcement division of the Securities and Exchange Commission, stood triumphantly in front of a group of reporters and an array of television cameras broadcasting his words globally. He announced that Goldman Sachs had agreed to pay a fine of $550 million—the largest penalty the SEC had ever imposed on a Wall Street firm—to settle a civil fraud case the agency had filed only months earlier. But Khuzami and the SEC had won more than their $300 million share of that settlement: Goldman had agreed to acknowledge publicly that the "fundamental basis" of the agency's lawsuit was accurate. Goldman had failed to live up to its own standards and disclose everything that German bank IKB might have wanted to know about the mortgage securities deal, dubbed Abacus, that lay at the heart of the suit. Specifically, the SEC had claimed Goldman hadn't fully explained to IKB and other potential investors buying the Abacus package of synthetic mortgage-based securities that hedge fund manager John Paulson had played a key role selecting the specific securities in that transaction—indeed, that the deal was being done at his initiative because he wanted to find a way to profit from what he expected would be a big decline in the value of the securities he chose. That's precisely what happened: Paulson walked away a billion dollars richer, while IKB became one of the first financial institutions to fall victim to the global financial crisis and require a bailout.

Goldman Sachs, the envy of Wall Street, now found itself under scrutiny for all the wrong reasons. Instead of its peers and rivals trying to figure out what it was doing to earn the astonishing rates of return it delivered like clockwork to its investors, regulators and legislators were putting its business under a microscope. To insiders, it seemed as if everything for which Goldman was once famous and lauded—its creativity in devising and structuring new products; its risk management prowess; the market insight displayed by traders deploying the firm's own capital to generate returns; the firm's ability to develop relationships with power players in Washington as well as on Wall Street—now rendered it infamous. Suddenly, everyone was asking what Goldman Sachs had

done to earn the gargantuan profits in recent years; profits that had left other Wall Street CEOs green-eyed with envy and fuming at their own inability to measure up.

But this book—conceived in early 2008, as Bear Stearns collapsed and Wall Street waited, holding its breath, for the next shoe to fall—is not the story of the transformation of Goldman Sachs from Wall Street's most envied to its most reviled power. Rather, it's the tale of the ways in which Goldman and the other Wall Street firms that sought to emulate its success underwent a fundamental transformation, and the impact of those changes for Wall Street, its clients, and the financial system as a whole. That transformation—which led to Wall Street being run solely in the interests of Wall Street entities themselves, with clients now viewed as counterparties—paved the way for the financial crisis whose ripple effects continue to reverberate on both Wall Street and Main Street. For the latter—indeed, for most of us—Wall Street's value lies in its role as a financial utility or intermediary. But as the financial results of Goldman and its rivals demonstrated all too clearly, that's not where the profit lay. And ever-bigger profits were what Wall Street's own investors—the shareholders who bought stock in Goldman Sachs, Merrill Lynch, Lehman Brothers, and other firms—demanded, loud and clear.

The SEC's fraud lawsuit against Goldman Sachs simply made public what many Wall Street insiders had long known: clients need to be able to look out for themselves. Wall Street firms are dealing cards from the bottom of the deck to their friends, while saving the low-value cards for other clients. In case there was any doubt of what Goldman bankers really thought of the deals they were taking to their clients, investigators rapidly made public a series of embarrassing e-mails and other documents. In one, top Goldman banker Tom Montag wrote of another mortgage-backed securities transaction—Timberwolf—that it was "one shitty deal." Certainly by the time John Paulson came knocking on its door, Goldman knew that being "long" subprime real estate in the spring of 2007 was likely to be a risky bet for anyone agreeing to take the other side of the trade that Paulson wanted to do: after all, the firm was pushing

its team to unload their own exposure to others as rapidly as possible. In an e-mail to a friend, Fabrice Tourre, the banker who structured the deal (and who has not yet been able to settle the SEC's charges against him) wrote of the CDO transactions he was crafting, "the whole business is about to collapse any time now … Only potential survivor, the fabulous Fab!" In another e-mail, the head of Goldman's structured products correlation trading desk warned Tourre that "the cdo biz is dead" and that "we don't have a lot of time left." None of that gave Goldman Sachs bankers a reason to stop, it seems. Even Bear Stearns had turned away John Paulson, concerned at the ethical implications of allowing a hedge fund manager to choose which securities he would bet against and thus which securities Bear would have had to coax a client to buy outright.

"In the old days, we would never have done business with just anyone who showed up on our doorstep," insists one former Goldman Sachs partner, who says the revelations left him "shocked and dismayed." In the old days, before Goldman Sachs sold stock to the public and its culture began to change irrevocably, "the question would have been 'John Who? Do we know this guy? What is he asking us to do? What are the consequences of this? Is this someone we want and need a relationship with?' Above all, we were always prepared to say 'no.' "

But by the dawn of the twenty-first century, saying "no" to deals wasn't how Wall Street worked anymore. From the mortgage brokers who underwrote the now-notorious "no income, no-docs" home loans all the way up to the investment bankers who just couldn't turn away a John Paulson, even when they had ethical reservations or, as Fabrice Tourre admitted, the securities that they were creating for their investors were "monstrosities"; the very word "no" seemed to have vanished from the lexicons of those toiling within the financial system. And the pressure was on to say "yes" to any deal that could generate a few pennies a share in quarterly earnings, because each and every investment bank and commercial bank was well aware of the extent to which its own return on equity fell short of that being generated by the Midas-like

bankers at Goldman Sachs. Swiss banking giant UBS hired a consulting firm to advise it on the best way to generate profits; Goldman alumnus Robert Rubin, who had moved on to work for Citigroup, only reluctantly acknowledged to colleagues that his new firm had neither the trading skills nor the risk management prowess to beat Goldman at its own game. (That didn't stop Citigroup from trying, of course.) Top bankers at Merrill Lynch & Co. knew to steer clear of their temperamental CEO Stan O'Neal on days that Goldman Sachs released its earnings. "Why can't we earn numbers like that?" he demanded of one subordinate in mid-2005.

The problem for Wall Street wasn't what Goldman Sachs did. It was the attitude that lay behind those actions, combined with the fact that its rivals and eager imitators tried to beat Goldman at its own game. When O'Neal's underlings set out to beat Goldman's return on equity, they succeeded in wiping out a decade's worth of profits by taking gargantuan risks in collateralized debt obligations (CDOs) made up of subprime mortgages. The fallout from UBS's effort to chase Goldman Sachs cost the Swiss bank billions of dollars in losses and writedowns. So far, much of the scrutiny of the financial crisis has been devoted to identifying and analyzing its proximate causes: the boom in risky, subprime lending; the role that securitization and derivatives played in amplifying that risk and spreading it throughout the financial system; and the inadequate risk management methodologies that were exposed by the crash. These are easier to understand and to grasp—but they also create the illusion that since we can name them so readily, they can be fixed with a few well-considered and carefully designed reforms.

There are deeper-seated causes, however, that are far more significant systemic issues that both Wall Street and Washington have yet to address. What purpose does Wall Street serve? What do we have to do to restore public confidence that it can act in the interests of all its stakeholders, not merely those who run it and view it as a way to generate vast profits for themselves? Certainly, Goldman Sachs envy hasn't abated on Wall Street, even if most of its rivals admit that they'd prefer to be known for its Midas touch

than the Abacus transaction. And as long as they keep chasing Goldman Sachs, and what Goldman is doing to earn its hefty profits is weakening the integrity of the financial system, then real reform is still far distant. The Financial Crisis Inquiry Commission's final report touched on this when it noted that both bankers and regulators "ignored warnings and failed to question, understand and manage evolving risks within a system essential to the wellbeing of the American public. Theirs was a big miss, not a stumble." Nor were those members of the FCIC who signed on to the report optimistic about the future. "Some on Wall Street and in Washington with a stake in the status quo may be tempted to wipe from memory the events of this crisis."

True, the playing field has never been a level one for those on Wall Street. Back in 1940, Fred Schwed wrote what has now become a classic book, Where Are the Customers' Yachts? In it, a visitor to Manhattan is being shown the sights near Wall Street, including a yacht basin around the Battery. "Look, those are the bankers' and brokers' yachts," his guide points out. "Where are all the customers' yachts?" asked the naive visitor. The punchline was obvious: Wall Street didn't make enough for its clients for them to own yachts. Not much has changed, except that in the wake of the financial cataclysm, some of Wall Street's customers have begun to feel as if they are setting out to sea in leaky rowboats, without their bankers and financial advisors being either ready or willing to dispatch a life raft in case of emergency.

The reason Wall Street exists and the reason it was bailed out by the American taxpayer is that it plays a vital role in our capitalist economy. We need Wall Street—and we need Wall Street to remember that function. But today's Wall Street is far from serving that "utility" role, and it remains to be seen whether the regulatory reform proposals will convince Goldman Sachs and its rivals to reconsider their raison d'être and redefine their responsibilities to both their clients and to the financial system itself. None of the survivors can resume chasing Goldman Sachs and lusting after its profits if what Goldman Sachs does and the others try to do in order to earn that rate of return succeeds in undermining the health of the

financial system as a whole. If there is one lesson we all, from the Oval Office on down, need to learn from the crisis, that's it.

INTRODUCTION

The Chase

"Does Wall Street owe the American people an apology?"

Tom Casson* heard the question—the one on the minds of every American taxpayer furious at the very idea of footing the bill for Wall Street's excesses in the shape of the $700 billion bailout package under debate in a Senate hearing room—from the television on the trading floor just outside his office. He saw himself as part of Wall Street—it was where he had spent nearly all his working life—so the very idea that some senator from who knows where thought he should apologize to the country piqued his curiosity immediately. "Why would I and the rest of my guys do that?" he wondered. Still, listening to either Treasury secretary Henry "Hank" Paulson or Federal Reserve chairman Ben Bernanke struggle to answer the question in a way that would keep the members of the Senate Banking Committee happy had to be more fun than just watching the red lines on his Bloomberg terminal that signaled stock and bond market index levels inching their way lower and lower with every passing minute. In search of distraction, Casson got up from behind his desk and ambled toward the trading floor. Leaning against the glass wall that separated his small fiefdom from the hurly-burly of the floor, he waited for the answer.

It wasn't what he expected to hear. After a lot of hemming and hawing, Ben Bernanke finally replied that to most of America, "Wall Street itself is a … is a … is an abstraction." Casson felt as if he'd accidentally stuck his finger in an electrical socket. He stood upright, staring at the television in astonishment. What had Bernanke just said? Can he really have just described Wall Street as an abstraction? In Casson's eves. Wall Street couldn't be less abstract

—it's where businesses find capital, where investors with capital find places to put it to work in hopes of earning a return. Over the decade that he had toiled on the Street, Casson had raised money for some of those companies and helped others to negotiate multibillion-dollar mergers. Now the politicians were demanding that he and his colleagues apologize for what they spent their lives doing? Even worse, the head of the Federal Reserve—the individual who was the public face of banking regulation and monetary policy making—couldn't find a better word to describe Wall Street than abstraction. Months later, Casson was still bemused. "How could anyone say that Wall Street was an abstraction?" he wondered aloud. What had happened to make even the Fed chairman blind to Wall Street's real value?

The details of what happened during the weekend in September that preceded those Senate hearings, the weekend of frenetic deal making, hectic negotiations, and never-ending meetings within the Fed's fortress-like New York headquarters involving nearly every top figure on Wall Street, have by now been told and retold. We know that Merrill Lynch held its board meeting to approve the sale of the firm to Bank of America at the St. Regis Hotel in Manhattan; that Securities and Exchange Commission (SEC) chairman Christopher Cox accused a British counterpart of being "very negative"; that Hank Paulson commuted to the negotiations downtown from a suite at the Waldorf Astoria in midtown Manhattan. We even know the favorite route for the dawn runs by Timothy Geithner (then head of the New York Fed, who would succeed Paulson at the Treasury Department in the New Year) along the southern tip of Manhattan.[1] We know what happened—the names of the firms that failed, and those that rapidly returned to making money hand over fist. (We still don't know the names of those institutions saved from disaster by last-minute help from the Treasury Department, but if media organizations make a compelling freedom-of-information case to the courts, that information won't be long in coming.) We know the proximate

causes of the crisis: too much leverage, too much risk, and too much subprime lending.

This book will take you on a different journey. Instead of rehashing every detail of what happened to Wall Street, I'll take you behind the scenes and show you just why our financial system came so close to falling over the edge of the abyss. How did we reach the point where Wall Street was in so much jeopardy that the staid and somewhat self-important Paulson was willing to go down on one knee in front of House of Representatives Speaker Nancy Pelosi—a Democratic politician most investment bankers distrusted and even roundly disliked—to beg for her assistance in passing a financial aid package for the surviving firms, including his own alma mater, Goldman Sachs? Above all, what had happened to Wall Street that Bernanke could describe it as an "abstraction" and be greeted not with howls of outrage or confused questions by his audience but rather with nods of acknowledgment and understanding?

Truth is, Wall Street isn't an abstraction but a kind of public utility. That's a characterization liable to make those who work on the Street bristle in indignation. But in many ways, the financial system of which Wall Street is a critical part bears an uncanny similarity to any power company or water system. When you come home at the end of the day, you count on being able to flick a switch and see your lights come on; in the morning, you rely on being able to turn on a tap and get clean running water for your shower. You almost certainly rely on Wall Street in the same unconscious way. Wall Street offers us an array of investment ideas for our retirement portfolios; Wall Street institutions finance our entrepreneurial dreams and lend us the capital we need to help us buy homes, cars, and even birthday gifts for friends and family. (Sure, they make money doing that—but so do the power company and the water company.)

From its inception Wall Street had been there to serve Main Street, and it took that role seriously. "It was valued; serving your corporate clients, if you were an institutional firm like Morgan Stanley, or investors, if you were a retail-oriented firm like Merrill

Lynch, exceedingly well was the ticket to success on Wall Street," says Samuel Hayes, professor emeritus at the Harvard Business School. The problem is that from the 1970s onward, serving as a public utility and performing these intermediary functions for the people on both ends of the "money grid" (investors and companies needing capital) just wasn't as profitable as it used to be.

That's the starting point for this book, which will explain just how and why Wall Street drifted away from its core intermediary function and morphed from utility to casino, under pressure from those running Wall Street firms and from their investors. Both of those groups put a priority not on fulfilling Wall Street's role as a utility but on finding the most profitable products and business strategies, of which subprime lending and structured finance were only the latest—and, so far at least, the most toxic—manifestations.

Eventually, these insiders came to treat Wall Street as if it were any other business, only as valuable as the profits they could extract from it. Instead of turning to proprietary trading or structured finance only to supplement their returns from the less profitable utility-like or intermediary operations, many Wall Street firms deemphasized Main Street altogether in favor of catering to Wall Street clients: hedge funds, private equity funds, and their own principal investing and proprietary trading divisions. Nor were there any incentives for Wall Street residents to question their collective transformation from quasi-utility to self-serving, risk-taking, profit-maximizing behemoth. Compensation policies across the Street rewarded bankers and traders for turning a blind eye to the needs of the money grid; regulators—agencies charged with ensuring that utilities operate in the public interest—ended up catering to Wall Street rather than trying to rein in its worst excesses.

When utilities come under too much systemic stress, they fail. Think of the electricity system, and what happens when its managers fail to plan for the hottest summer days, when everyone turns on the air conditioner full blast and the demand for power peaks. Like millions of others living in the northeastern United States, I experienced that firsthand one muggy August afternoon in

2003, when the power to everything from elevators in high-rise office buildings to streetlights on Manhattan's busy roadways flickered off—and stayed off for much of the next twenty-four hours. Suddenly, I realized just how important the power grid was to my life. I joined thousands of others who had to walk home along the darkened New York streets, through the heat and humidity. Eight miles and many hours later, there was no cold water to ease the pain from my blistered feet (the lack of electricity had caused a plunge in water pressure) and no food (there was no way to cook anything); I couldn't even find a cold drink to revive me.

Thankfully, the reasons for the blackout were relatively straightforward. Someone had decided to take a power plant offline, meaning that its output wouldn't be available to customers on one of the hottest days of the year. A bad call. When electricity demand spiked, that put a strain on the high-voltage power lines. Since electricity companies know that can happen, causing power lines to sag dangerously low, they make an effort to keep trees and foliage trimmed back. That didn't happen at one utility—another bad call—and the power lines brushed against some overgrown trees, triggering a series of failures that cascaded throughout the region's power grid.[2]

The 2003 blackout was an accidental phenomenon. But imagine if in the years leading up to the blackout, the power companies had been overrun by a new breed of managers, extremely bright and imaginative engineers armed with MBAs. Imagine that they had been given a completely different mandate by shareholders: blackouts don't happen too often (the last big one was in 1965), so if preparing for one consumes too much capital or limits profits too much, don't bother with it. And imagine that those engineers, in order to maximize profits, decided to use all the money they had saved by not investing in backup capacity and maintenance to build and operate a casino, or some other business that would generate a much higher return in the short run. Finally, imagine that regulators were asleep at the switch and let them do it. Happy shareholders would have richly rewarded the engineers for their efforts right up

until the last minute. And even after the blackout (which would have been far more catastrophic and longer-lasting than that of 2003), while all of us were struggling in the dark, those investors and the engineers would have had more than enough money to buy their own generators to provide power to their mansions.

In a nutshell, that's what happened to Wall Street as it morphed from being an intermediary to being a self-serving, risk-taking machine for generating profits. As long as times were good, few participants stopped to ask questions about this transformation, including those who have today become some of the Street's harshest critics. And even now that we've experienced the near blackout of the financial system, the fingers of blame are pointing to individuals—Richard Fuld, at the helm of Lehman Brothers, for instance, or Christopher Cox, the chairman of the SEC, who looked the other way as Bernie Madoff ran his Ponzi scheme and as the investment banks his agency regulated teetered on the edge of disaster. If we ever are going to be able to devise wise policies for Wall Street and ensure the future health of the financial system, we have to take a hard look at more than just the proximate causes of the debacle, such as subprime lending or the activities of pot-smoking, bridge-playing Jimmy Cayne at Bear Stearns. We need to understand how to make the money grid work properly. Maybe just being an intermediary doesn't generate enough in profits to sustain the system anymore—but that doesn't mean that people running the utility should feel free to toss caution to the wind and start speculating on a host of new and risky businesses.

Bankers are trying to clear up the mess they have made, while in Washington, regulators and policy makers are running around in circles trying to analyze what went wrong and to put in place a new set of rules that will prevent the financial system from coming so close to the brink again. But none of these very smart people is either admitting to or acting on the biggest problem of all: the fact that while Wall Street is as important to our economy and society as any other utility, it doesn't work like one. Let's say that Morgan Stanley decided, as a result of the events of the last two or three years, to pare back the amount of risk it is willing to take. It shuts

down its proprietary trading desk, says it won't act as a principal and invest alongside its clients in businesses, and limits its involvement in risky products such as synthetic credit default swaps. It even decides to turn away underwriting assignments if its bankers conclude that the stocks or bonds the firm would be underwriting would add to the level of risk in the system. Instead, Morgan Stanley focuses on wealth management, on building a commercial banking franchise, or on market making (facilitating the two-way flow of trading in stocks or bonds). What would happen next?

Well, none of these is a high-growth business that will lead to big annual jumps in profitability. Before long, the impact of this decision would show up in the bank's quarterly earnings; with each fiscal quarter, the gap between Morgan Stanley and its rivals would widen, in both absolute levels of profitability and the rate of growth in profits. The bonus pool would shrink, and if this risk-conscious move was one that only Morgan Stanley had made on its own initiative (and not part of a government-mandated change affecting the entire industry), the bank's most talented and skilled employees would be lured away to work for competitors. Ultimately, the investors in Morgan Stanley, those who have purchased its stock in hopes of seeing the value appreciate, would stage a rebellion. It wouldn't take long before they'd protest to the bank's management team and demand that the managers do whatever it takes to keep up with the returns being posted by their peers. If those managers stick to their guns, the investors' next stop would be the offices of the company's directors. It's pretty easy for anyone to imagine what would happen next to the executives who had decided that shunning high-risk but profitable businesses was a good idea. "Give us a new management team, with some guts, that's willing to go out and do what it takes to capture whatever profits are going!" shareholder A would demand. Since the board's absolute duty is to maximize value for shareholders, it wouldn't take long for it to capitulate.

Do you think that couldn't happen? Well, it did, over the course of the last two decades. Over that period, Goldman Sachs emerged as the rival to beat, or at least to try to mimic. The firm seemed to

have a Midas touch: in the decade leading up to the financial crisis, it generated an average annual return of 25.4 percent on shareholders' equity, while the four other large investment banks earned an average return on equity (ROE) of 15 percent annually in the same time frame. No wonder Goldman's rivals were furious as they fended off complaints from their own shareholders. It was clear to every other Wall Street CEO that chasing Goldman Sachs was the only way to boost their personal wealth and simultaneously keep their cantankerous shareholders pacified.

What Goldman was doing, however, was something very different from the traditional business of Wall Street. By 2007, the year that it posted record profits of $11.6 billion and distributed a bonus pool that was even larger ($12.1 billion) among its employees, Goldman was getting only about a third of those earnings from serving Main Street clients; the rest came from investing and trading for its own account. It had become commonplace for Goldman's rivals to refer to the firm, scornfully, as a hedge fund disguised as an investment bank, even as they scrambled to mimic the strategy. The problem was that they weren't moving into these businesses because they believed they had a competitive advantage or the most talented bankers and traders. They were doing it just to keep pace with the market leader. And while Goldman Sachs, as we'll see, managed to steer clear of some of the subprime mess, those firms that were just trying to chase Goldman Sachs didn't have the tools or the people to help them properly manage the new risks they were taking.

During those years, when everyone was chasing Goldman Sachs, there was every incentive to just keep doing so and not much encouragement to stop and rethink the strategy. John Costas, former head of investment banking at UBS and one of the Swiss bank's most powerful deal makers, says the system worked in such a way that everyone was under pressure to do whatever it took to grab the extra percentage point of market share or return on equity and to ride roughshod over naysayers. "For a decade, from 1999 through the middle of 2007, anytime you stopped participating, by not adding more risk or by not aggressively pursuing more transactions,

you were wrong." In other words, chasing Goldman Sachs was a strategy that paid off for so long that Wall Street's leaders were ill equipped to recognize that it might not always continue to do so.

Nor was it possible to sit out the dance, to not try to emulate Goldman's golden touch. With the benefit of twenty-twenty hindsight, deciding back in 2003 or 2004 not to get caught up in the business of repackaging subprime mortgages into collateralized debt obligations (CDOs) looks great. At the time, it would have been untenable, says one former senior banker. "What was happening at the bank that did that? The investment analysts are downgrading it, the shareholders are unhappy, and the employees are unhappy because the bonuses aren't as fat as those their friends are earning. The press is all over the bank, saying it's not as well run as the other bank." That, he argues, is the kind of thinking that sealed the doom of some of Wall Street's most venerable names.

That kind of thinking is still alive and well on Wall Street today, even after the near apocalypse. The quest is already under way for the next "new new thing," the next product or strategy that will help firms such as Goldman Sachs and its rivals earn massive profits in the short run while creating new risks for the financial system. Perhaps it will be something that Goldman Sachs pioneers, or something that is launched by one of the new boutique institutions. The one certainty is that Wall Street's mind-set remains unchanged. Left unchecked, every firm will again overlook risk in hopes of gaining a dominant market share in that new product. The financial system has been saved from destruction, but as long as the mind-set of "chasing Goldman Sachs" lingers, it hasn't been reformed.

As the worst of the crisis recedes into the distance and Wall Street battles to return to business as usual, Goldman Sachs is once again the firm that all its rivals want to emulate, at least when it comes to financial performance. As David Viniar, the firm's chief financial officer, told a reporter in 2009, "Our model never really changed"[3]; by the end of 2009, Goldman was again rewarding its employees with one of the biggest bonus pools in its history and had returned to reporting astronomically high earnings. Once again, a relatively small proportion of those profits came from serving Main Street.

Wall Street is still oriented toward serving itself—its shareholders and employees—and as long as that collective mind-set endures, we run the risk of another systemic shock.

There is no point sitting around and waiting for Wall Street to apologize to us, individually or collectively. Nor can we content ourselves with the idea that bankers are twenty-first-century cartoon villains and demand that they get their just deserts. It's not even reasonable for us to indulge in bouts of nostalgia for the banking system of the past. True, in hindsight, the 1960s look like a golden age but we can't just wipe out innovations such as high-speed trading based on computer algorithms that didn't exist then. Nor can we force investment banks to return to the days when they weren't large publicly traded corporations but partnerships that valued long-term relationships over short-term quarterly profits. We can't turn back the clock to a time when hedge funds and private equity funds were a tiny sideshow on Wall Street. What we can and must do is understand the way Wall Street functions today and try to align that more closely with its special role in our economy and society.

This book isn't another anecdotal history of the subprime crisis of 2007 and 2008. Rather, it's the tale of how Wall Street's metamorphosis from a utility serving Main Street to a business that took extraordinary risks to maximize its own profits at the expense of that utility function set the stage for that crisis. It's an analysis of where we stand today and where we need to go next—to a world where, instead of blindly chasing Goldman Sachs in hopes of replicating its success, the players that make up Wall Street identify ways to emulate the strengths and avoid the flaws that lie within the business model of Goldman Sachs and seek out their own paths to success. Above all, those strategies must be based on their own competitive strengths and be pursued in a way that doesn't jeopardize Wall Street's core utility function.

The story is told through the eyes of those who lived it, such as Tom Casson—the bankers, traders, research analysts, and investment managers who have spent the bulk of their professional lives on Wall Street. Some of them can recall firsthand the events of the

1970s, when new technologies and new rules began to reshape the world they inhabited. It's the story of how Wall Street came to be seen, even by one of its devotees, as an "abstraction." With any luck, the next time Bernanke uses that phrase to describe the money grid, he'll be met with howls of outrage.

* Here and throughout the book, a name followed by an asterisk is a pseudonym for a all Street professional. Casson, as is true of many of his colleagues still working on Wall Street, does not have permission to speak openly to the press or book authors about what they see happening around them; while their CEOs do, it's rare to find them frank and forthcoming. In cases such as that—where speaking openly and honestly about what individuals on Wall Street witnessed and experienced would have caused trouble for my sources with their employers or investors, and where simply using an anonymous source would have made following the narrative unnecessarily difficult for the reader—I have chosen instead to gives these sources a pseudonym. In cases where that is done, their name is followed by an asterisk when they first appear. When senior Wall Street officials declined to be quoted on the record for this book, I have not given them pseudonyms, but simply cited them and referred to their roles on the Street, but not their firms. Reporting this book at the height of the crisis in the winter of 2008 and spring and early summer 2009 proved particularly challenging, as many of these individuals were focused on what was going to happen in the next twenty-four hours or the following week, not what happened in past decades or what might happen over the next decade. "How can you ask us to predict that?" said Fred Joseph, former boss of junk-bond king Michael Milken, who went on to cofound a boutique investment bank but who, sadly, died in late 2009. "We can't predict what we'll have to deal with in a month or two, and how that will change our options." This book reflects the views and thoughts of some two hundred individuals whose lives are tied to Wall Street in one way or another and who, like Joseph, made that effort.

PART I

DANCING TO THE MUSIC

The financial markets had begun to feel the first shocks of what would become the worst market earthquake since the Great Depression when, in July 2007, then–Citigroup CEO Charles "Chuck" Prince came up with an unusual metaphor to explain why he and his team were forging ahead with business as usual, making loans to private equity funds to help finance the increasingly gargantuan buyout deals the latter were trying to structure. Sure, the credit markets were rocky, raising fears among some market participants that big banks like Citigroup—those that had been the most aggressive lenders to the LBO community and the biggest participants in the world of structured finance, marketing securitized products and derivatives to clients—would get stuck holding too many of those loans if there were no willing investors to take them off their hands. Prince, too, may have been worried, but he wasn't going to show it. Instead, he told the Financial Times, "as long as the music is playing, you've got to get up and dance." And, he added, Citigroup was "still dancing."[1]

That music came to a sudden and discordant end only months later, by which time Prince himself had been ousted as the giant bank's CEO. Citigroup was still paying the price for his philosophy years later. In order to prevent collapse, the bank had to accept government bailout funds, a portion of which was later converted into stock that gave the federal government an ownership position in Citigroup. Write-downs produced a gargantuan loss—$27.7 billion—in 2008; while the bank's 2009 loss of $1.6 billion was a lot smaller, it stood in stark contrast to the big profits being earned by the likes of JPMorgan Chase and Goldman Sachs.

How and why did one of Wall Street's premier institutions end up in such a pickle? The story of why Prince felt it necessary to keep dancing as long as the music played is one that has its roots back in the late 1960s and early 1970s, long before Citigroup existed or Wall Street had ever heard of collateralized debt obligations, credit default swaps, multibillion-dollar buyout funds, or any of the other instruments or players now often cited as culprits in the meltdown of the financial markets. The story of

Citigroup—both its rise and near collapse—hinges on the changes to Wall Street's very structure. Without those transformations—some of them slow and almost imperceptible; others, like the collapse of the 1933 Glass-Steagall Act mandating a strict separation between investment and commercial banking, grabbing headlines worldwide—Wall Street could not have become as powerful a player in the U.S. economy as it did. Equally, it would not have endangered the entire money grid.

During the opening session of the hearings of the Financial Crisis Inquiry Commission (FCIC), Mike Mayo, a veteran banking analyst and now a managing director at Calyon Securities (USA) Inc., described Wall Street's member firms as being "on the equivalent of steroids. Performance was enhanced by excessive loan growth, loan risk, securities yields, bank leverage and consumer leverage.... Side effects were ignored, and there was little short-term financial incentive to slow down the process despite longer-term risks." But by the time the problems became so big that they began to nag at Mayo and many of his colleagues during the first decade of the new millennium, the trends that had led to those problems had been in place for decades. As I'll explain, the changes to Wall Street forced its financial institutions to rely on the most innovative and most leveraged products it could devise, because those generated the greatest profits. Similarly, the needs of "insiders"—Wall Street players like hedge funds and buyout funds—came to dominate the Wall Street landscape. As long as dancing to the music produced the profits that firms like Citigroup and its investors craved, they would continue to jig, two-step, or even produce a creditable Highland fling, if necessary. The first section of this book is the story of how that ethos became central to the way Wall Street functioned.

CHAPTER 1

From Utility to Casino: The Morphing of Wall Street

Alan "Ace" Greenberg's firm may have collapsed underneath him, but even in the darkest days of 2008, the eighty-one-year-old investment banker's legendary chutzpah was visible on Bloomberg's business television network. "There's no more Wall Street," Greenberg, the former CEO of Bear Stearns, declared, adding that it had vanished "forever" in the rubble.[1]

It's fashionable on Wall Street today to talk wistfully—or in a tone of reverential awe—about investment banking as it was practiced during what is now seen as a kind of golden era. Greenberg's comments, though more hyperbolic than most, are one example.

The changes over the course of 2008 were so dramatic that Greenberg believed the Wall Street he helped forge no longer existed in any kind of recognizable fashion. Some nostalgic Wall Streeters view the investment banking landscape of the 1960s, '70s, and early '80s as a kind of utopia: investment banking as its purest, before the 1987 stock market crash, the collapse of the junk bond market, and Gordon Gekko made Wall Street seem slightly reckless and disreputable. To others, Greenberg among them, the golden era is the more recent past, when investment banks such as Bear Stearns saw their revenues and profits soar as they catered to the emerging powers on the Street, hedge funds and giant buyout funds, and watched their bonus payments and personal wealth climb even more rapidly.

The balance of power has certainly shifted on Wall Street, and new products, players, and technologies have transformed it. But Greenberg's comments were directed at the collapse of specific

institutions: the shotgun wedding of his own firm with JPMorgan Chase, the bankruptcy filing of Lehman Brothers, and, the same weekend, the flight of Merrill Lynch into the arms of Bank of America. Greenberg most likely knew about the behind-the-scenes wheeling and dealing orchestrated by Ben Bernanke and Hank Paulson that involved every conceivable combination of every Wall Street firm with every one of its rivals (J.P. Morgan and Morgan Stanley? Goldman Sachs and Citigroup?). The desperate rush to save the financial system from utter collapse had resulted in the kind of merger negotiations—however short-lived—that would have seemed laughable only weeks earlier. To Greenberg, still reeling at the collapse of his own firm (which had, after all, survived even the 1929 market crash and the Great Depression), that must indeed have felt like the end of Wall Street.

Wall Street, however, is more than just a set of institutions with big brand names, however old and venerable. At its heart, it is a set of functions, and those functions remained intact even in the midst of the crisis. Two days before Greenberg delivered his epitaph for Wall Street, a small Santa Barbara company, RightScale, raised $13 million in venture capital backing from a group of investors led by Silicon Valley's Benchmark Capital.[2] RightScale's secret? It was in the right business—cloud computing, a way for customers to reduce their IT development costs by using Internet-hosted services—at the right time. Despite the dramatic headlines focusing the world's attention on the plunge in the stock market and the deep freeze that hit the credit markets, parts of Wall Street's core business were still functioning, albeit in a more muted fashion. In the final three months of 2008, venture capital firms invested $5.4 billion in 818 different deals, bringing the total for the year to $28.3 billion. That was down a bit from 2007, when venture firms—partnerships that have made fortunes backing companies such as Amazon.com and Google and lost smaller amounts backing stinkers such as Pets.com—put $30.9 billion to work. But it's still more than they invested in any year from 2002 through 2006.[3] By the first anniversary of the collapse of Lehman Brothers, even the high-risk world of junk bonds was back in business. The sign? Beazer Homes, one of the

worst-hit home-building companies in the entire industry, was battling not only the collapse in the real estate market but also a federal fraud investigation. Yet Wall Street found enough investors willing to close their eyes to those risks and invest $250 million in junk bonds issued by the company to help replenish its coffers.[4]

What Does Wall Street Do, and Why Does It Exist?

The reason for the Wall Street bailout—the explanation for Hank Paulson being desperate enough to literally drop to one knee in front of Nancy Pelosi in the White House and plead for her help passing the initial $700 billion rescue package—is that Wall Street's functions are essential to the economy. According to reports that were leaked to the media almost immediately, Paulson begged Pelosi not to "blow it up" (referring both to the bailout package and the financial system itself) by withdrawing the Democratic Party's support for the rescue effort. "I didn't know you were Catholic," Pelosi quipped, referring to Paulson's kneeling before her, in an effort to lighten the atmosphere before blaming the Republicans for the gridlock.[5]

By saving some of Wall Street's institutions—those viewed as the strongest or the most important to the system—the architects of the bailout and many of the subsequent reform packages hoped to preserve intact the system that enables capital to flow more or less smoothly through the economy the way power flows through the electrical grid or water through a municipality's water and sewer system. Regardless of what Main Street was thinking—and communicating to their members of Congress—Wall Street isn't incidental to what happens in the rest of the economy. Without Wall Street to perform its financial grid functions, it would prove almost impossible to raise capital to repair bridges, finance new companies such as RightScale, and keep others—such as Beazer Homes—afloat.

What we tend to think of as Wall Street—the stock market, the investment banks, and the newer entities such as hedge funds—is

really only the visible tip of a much larger iceberg that is the entire financial system. Collectively, these institutions help ensure that capital continues to move throughout the rest of the "money grid." Sometimes they do this by providing a market for participants to undertake basic buy or sell transactions; on other occasions, they negotiate or devise solutions to more complicated capital-related questions, such as helping a company go public or sell debt (a process known as underwriting) or working with it to establish and achieve the best price possible in a merger negotiation.

That intermediary function is alive and well, most visibly at the New York Stock Exchange, which occupies not only the epicenter of Wall Street at the corner of Broad and Wall Streets but the heart of its role as a financial utility. On its sprawling trading floor, traders go about their business in much the same way their earliest predecessors did in the naves of Amsterdam churches, executing the purchases of blocks of shares for their clients, who these days could include an individual trying to sell 100 shares of General Electric or Microsoft inherited from a grandparent or a mutual fund manager trying to reduce his holdings in Amazon.com in order to buy a stake in Alibaba.com, a Chinese counterpart. Exchanges trading stocks, futures, and options contracts as well as commodities remain one of the most heavily regulated parts of Wall Street because of the essential role they play in a large, geographically scattered, and diverse community.

Not convinced of the value of Wall Street's functions and processes? Imagine you are a retiree in your seventies, living off your investment portfolio. The wisdom of your decision to invest in Microsoft in the mid-1980s has become clear; now you're counting on being able to sell some of that stock at its current market value in order to cover your living expenses for the next six months. Wall Street's processes make that relatively simple—all you have to do is place an order to sell the stock at the market price with your broker or custodian (say, Charles Schwab) and ask for the money to be transferred to your bank account when the trade is settled in three days' time.

Now, imagine that there was no Wall Street. For starters, you'd

have a hard time establishing a fair price for that stake in Microsoft without the stock market, with its countless numbers of buyers and sellers meeting in cyberspace to decide each millisecond of the day what value they ascribe to Microsoft's shares and thus what price they are willing to pay for your stock. Even if you thought you knew what your shares were worth, how would you find a buyer and persuade her that your analysis is right? Would you go door-to-door in Miami or Los Angeles? Put up an ad on Craigslist? (In Vietnam's over-the-counter market, that is exactly what happens; you then arrange to meet the buyer on a street corner to swap the shares for cash.) And if you found a buyer, could you be certain that you would be paid in full and on time, so that you could pay your own mortgage and purchase your groceries?

Money has existed for millennia, ever since people recognized that barter was an inadequate method of exchange. The stock exchange, just a few centuries old, was the next logical step as society's financial needs became more complex. The first exchanges were established in wealthy trading cities such as Hamburg, Antwerp, and Amsterdam. Here, by the early sixteenth century, there was a significant concentration of wealth in the hands of merchants and noblemen, all of whom had an interest in putting it to work in new and different kinds of enterprises in the hope of diversifying and making still more money. These communities traditionally were also home to cutting-edge commercial enterprises, ranging from new technologies such as printing to global trading ventures to the East Indies.

Investors willing to back these enterprises—most of which could take years to pay off—needed a secondary market: a place where people who were interested in buying or selling shares in ventures could meet each other or find an intermediary to help them with that transaction. For a while, Amsterdam's church naves served that purpose, along with the open-air wharves on Warmoesstraat near the city's old church, or Oude Kerk. The first formal stock exchange in Amsterdam opened its doors in 1610; between noon and 2:00 p.m. each business day, members were expected to show up and buy and sell on behalf of the general public—in other words, to

provide liquidity to the secondary market.[6] By 1688, the Amsterdam exchange already looked a lot like the trading floor of the New York Stock Exchange in its twentieth-century heyday; seventeenth-century stock jobber Joseph de la Vega, in his dissertation on the financial markets of the time, entitled Confusión de Confusiones, famously described the scene as one in which "handshakes are followed by shouting, insults, impudence, pushing and shoving." (Perhaps it was this atmosphere that led so many former professional football players to pursue second careers in the trading pits of the Chicago Board of Trade and the Chicago Mercantile Exchange.)

There probably has never been a time when people didn't complain about how the financial system worked—or failed to work. Nevertheless, the United States, as Alexander Hamilton, the country's first Treasury secretary, realized, would need a smoothly functioning financial system as part of its struggle to emerge as a viable nation-state.[7] Hamilton's initiatives included creating the country's first national or central bank, the First Bank of the United States, to replace myriad institutions within each of the thirteen original colonies, each of which had its own monetary policy and issued its own currency. Hamilton's goal was financial order and transparency, necessary if the new country was going to be able to repay its war debt and finance its growth by investing in new industries.

Wall Street, the narrow thoroughfare in lower Manhattan that owed its name to its former role as the northern border of the sixteenth-century Dutch colony of New Amsterdam, benefited from many of Hamilton's efforts to create the infrastructure of a national financial system and emerged as the heart of the new country's financial markets. It was here merchants chose to hang out on street corners to swap their ownership interests in government debt or the handful of start-up companies, such as canal construction ventures, that would form the core of the United States' new economy. (If you wanted to trade in the bonds newly issued by Alexander Hamilton's fledgling Treasury Department, you'd have to know which lamppost on Wall Street to stand under.) Eventually, the

introduction of New York state regulations banning curbside haggling as a "pernicious" practice drove these early Wall Streeters indoors. Some two dozen dealers gathered under a buttonwood tree to sign a pact that served as the foundation of the New York Stock Exchange. First housed informally in a Wall Street coffeehouse, the exchange moved to a room at 40 Wall Street in 1817, paying $200 a month in rent, before relocating to the quarters it now occupies, just across Wall Street from Federal Hall. Today, the original Buttonwood Agreement, a tiny sheet of yellowing paper, is on display at the Museum of American Finance a few doors away at 48 Wall Street, the building that once housed the Bank of New York, also founded by Hamilton himself.

"You know, if Hamilton came back to life, I don't think he'd be all that surprised at the way the financial system has evolved," says Dick Sylla, the Henry Kaufman Professor of the History of Financial Institutions and Markets at New York University. A silver-haired, slightly built man, Sylla appears unruffled by the dramatic changes that have taken place on Wall Street, smiling wryly at a display at the museum featuring Citigroup's now-reviled leaders—Robert Rubin, Sandy Weill, and Charles Prince. But then, for him as for Hamilton (about whom he is writing a book), America's financial system was never about a single institution, however large. "It's all about the functions that the various institutions perform, rather than what names they go by or where their headquarters happen to be," Sylla explains. "Hamilton knew that there would be bubbles and periods of chaos. But if over the long run the system as a whole performs its function of allocating capital and allowing us as investors to diversify our portfolio, to not put all our eggs in one basket, it is doing what he wanted it to do."

The Nature of the Money Grid: The Intermediary

Wall Street, in its totality, involves more than what happens on the floor of the New York Stock Exchange or within the walls of any single investment banking institution. It has become a labyrinth of

many different groups and institutions, all of which have one thing in common: they make the whole money grid work more smoothly and more efficiently. Many of them work hundreds or thousands of miles away from Wall Street itself. In Tacoma, Washington, Russell Investments devises stock indexes widely used by mutual funds and other big investors; in Kansas City, a firm called TradeBot uses computer-generated models to exploit tiny differences in the price of different types of securities and trades—in only milliseconds—on that information, making markets more liquid; Chicago's options exchanges make it possible for investors to bet not on the direction of a stock's price but on the rate and magnitude of change in that stock price and the time frame in which the change will occur.

All of these players perform functions that link the "buy side," those who have capital and want to invest it profitably, and the "sell side," those entities in need of capital. "At its heart, when it is doing what it does best, Wall Street is a superb gatekeeper, making matches between investors and businesses, governments, or anyone else who needs to finance something," explains Mike Heffernan*, a former Morgan Stanley banker. The sell-side client could be a regional bank trying to resell portions of some of the loans it has made, a credit card company looking for an investment bank to package up its receivables into asset-backed securities for resale, a town in Indiana trying to find investors for the municipal bonds it must sell in order to finance new hospitals and schools, or a company trying to raise capital for expansion or to acquire a rival.

The sell side wants to get as much capital on the most favorable terms possible from the buy side—investors who range in size and importance from individuals to mutual fund conglomerates such as Fidelity, and include hedge funds, private equity funds, foundations, college endowments, pension funds, venture capital partnerships, and ultrawealthy individual investors such as Microsoft cofounder Paul Allen or financier George Soros. In a perfect world, the sell side would love free money—with no interest payable, no specific term for repayment, and no promises about increasing the value of the investment. It is the myriad institutions that collectively make up Wall Street that—in exchange for a fee—bring together the two

parties and negotiate a compromise: the terms on which the buy side is willing to invest some of its capital and the sell side is willing to agree to in order to get its hands on that capital. Banks have been fulfilling that kind of function in more limited ways for centuries: the Bank of Venice issued government bonds back in 1157 to finance its war with the Byzantine empire in Constantinople, and by 1347, as the Medicis rose to power in Florence, there were no fewer than eighty banks making loans and doing business in that city-state; a few years later, the Florentine authorities started a special credit fund that would give interest-free loans to distressed condottieri, or soldiers of fortune.[8]

But as the sums got larger and the members of interested parties on the buy side (investors) and sell side (individuals or entities in need of capital) expanded in size and number and their needs became more complex, the process of bringing them together got tougher, and Wall Street–like intermediary institutions arose to facilitate the procedure. If you were a former condottiere who had lost an arm fighting for Florence against its neighbor and rival city-state Pisa in the fourteenth century, you knew which bank to approach for your interest-free loan. But what about financing a decade-long voyage to Southeast Asia in hopes of finding the mysterious Spice Islands and returning with a king's ransom in the shape of black pepper, cinnamon, and nutmeg in the sixteenth century, or funding the development of the latest gene-based cancer therapies in the twenty-first century? Both require the right kind of buy-side backer. On its own, the sell-side entity (the merchant adventurer or biotech engineer) would squander weeks or months it could ill afford trying to raise the capital it needed. And it was only logical that these go-betweens—the investment banks and their predecessors, who made it their business to be familiar enough with all the deep-pocketed members of the buy side so as to quickly route the different investment opportunities to those they believed would have the most interest and the right risk appetite—should pocket a fee for that knowledge as well as for their skill in negotiating the terms of any investment.

Wall Street exists to help investors and those in need of capital

find their way through the financing maze. Investment bankers still not only link the two sides but also help them sort out what terms are fair for the kind of capital being sought. Wall Streeters weigh in on the relative merits of different kinds of capital as well, advising corporate chief financial officers when it will be cheaper in the long run to issue debt on which the company will have to pay interest periodically, or when it might be a better idea to sell a stake in itself to investors in a stock deal. If they opt to issue corporate bonds, what kind of debt do investors want to buy, and what interest rate will the buy side demand in exchange for capital? Without the processes that Wall Street collectively oversees, it's hard to see how that vital function in our economy would be filled. The U.S. Treasury could still issue bonds and sell them directly to citizens, and municipalities might be able to raise at least some of the money they need selling muni bonds to their own citizens. But the latter, at least, won't raise all the capital they could at the cheapest possible price without an intermediary to help them identify the maximum number of interested investors.

If we were still back in the early 1900s, the prospect of the collapse of the investment banking system wouldn't be quite as apocalyptic as it is today, at least as long as enough of the commercial banks remained in business. That's because well into the 1920s, corporate finance was largely a matter of bank loans—if you could persuade your local bank manager that your business idea was sound and that you were a good credit risk, then he would lend you what you needed to get going and perhaps introduce you to some other folks who would invest in the fledgling company.

The earliest backers of auto pioneers Henry Ford and William "Billy" Durant (who founded both General Motors and Chevrolet) were local businessmen willing to risk some of their own money on two of the ambitious pioneers trying to build and sell the new horseless carriages. Durant even orchestrated a bidding war between Flint and Jackson, two midsized Michigan towns, to decide which would become the corporate headquarters of Buick, the company that would later become General Motors. Flint won the battle (along with the future tax revenue and jobs for its citizens) when its

four banks and several carriage and wagon businesses, along with hundreds of other corporations and civic boosters, put up nearly $1 million in cash in exchange for stock in the fledgling company, more than double what Jackson's citizens were able to offer.[9]

Financing these entrepreneurs was both risky and nerve-racking: two-thirds of the more than five hundred car companies launched between 1900 and 1908 had either collapsed or changed their business within a few years.[10] Once a bank or a backer had committed its capital to a specific venture, there were few exit strategies—the stock wasn't publicly traded. This early version of the money grid was unsophisticated and underdeveloped. Even Durant—far easier to work with than the mercurial Ford, and a former stock trader to boot—couldn't penetrate Wall Street's establishment and get the money grid working for the benefit of his company. Discussing the possibility of forming a trust made up of the biggest automakers to design and build a car for the mass market with J. P. Morgan's minions, Durant failed to persuade the great man himself of the virtues of the automobile. Much as he loved the idea of an oligopoly, Morgan seemed to love his horse-drawn carriage still more, dismissing automobiles as toys for the rackety younger generation and Durant as an "unstable visionary."[11] Durant was no more enamored of Morgan. "If you think it is an easy matter to get money from New York capitalists to finance a motor car proposition in Michigan, you have another guess coming," he wrote bitterly to his lawyer. Ultimately, Durant relied on local financing to get his new venture, General Motors, off the ground. Henry Ford managed to steer clear of Wall Street until the end of his life, relying on a steady flow of loans from banks such as Old Colony Trust Co.

Today's money grid is altogether a far more sophisticated and effective entity, having expanded geographically and evolved functionally. Wall Street is no longer a small clutch of giant investment banks, but includes a large and diverse network of venture capital funds whose specific function is to underwrite risky start-ups of the kind that Ford and Durant sought financing for a century ago and that a new generation of automotive industry

entrepreneurs are trying to launch today. “This is what we exist to do,” says Dick Kramlich of New Enterprise Associates, one of the venture industry’s veterans. “Until the postwar period, and even for a while after that, if you wanted to start something completely new, your personal network needed to include people who had money or who could vouch for you to the bank. Now all you need is a great business plan that you can get in front of one of us. We’ve become part of the bigger, broader Wall Street system.”

Indeed, during the Internet boom in the 1990s, Sand Hill Road, the long and winding thoroughfare that connects downtown Palo Alto, California, with the campus of Stanford University and other parts of Silicon Valley, became a kind of Wall Street west as the venture capital funds that set up shop there became more important to both the economy and the financial markets, financing start-up companies and generating big paydays for their own backers when some of those—eBay, Amazon.com, Netscape, and Google, to name a few—hit it big. Of course, just as many of the ships that sixteenth-century merchants financed in their voyages to the Spice Islands of Indonesia ended up dashed to pieces against the rocks on the coast of Africa, so many of the start-ups that today’s venture capitalists back never live up to expectations or go belly-up. But the winners have been frequent enough that venture capital investors willing to wait five, six, or even ten years for their bet to pay off in their little corner of Wall Street can make just as much money as top-flight investment bankers or superstar hedge fund managers in theirs.

At the height of the dot-com boom in 1999, commercial real estate on Sand Hill Road was more expensive to rent than anywhere else in the world (including Manhattan and London’s West End), reflecting the triple-digit returns some venture funds were earning. That bubble popped in 2000, making office space in Silicon Valley affordable again. But the venture capital community continues to scour the landscape for the next “new new thing,” whether that is the social networking “industry” or green technology, with businesses built around environmentally friendly twists on the pioneering products of a century ago, such as new

kinds of batteries, power generation technologies, and—yes, you guessed it—new kinds of automobiles. Detroit's executives might have had to grovel for a share of bailout funds after their financial prospects became so bleak that Wall Street east couldn't do anything to help. But on Wall Street west, some of Sand Hill Road's venture investors were eagerly backing companies such as Tesla Motors, founded by Elon Musk, the millionaire creator of the electronic payments system PayPal.

"A few years ago, this was the lunatic fringe of the venture capital industry," explains Ira Ehrenpreis, a general partner at Technology Partners, one of Tesla's financial backers. Today, he estimates, as much as $17 of every $100 that venture funds collectively invest goes into clean-technology companies as a category, while half of all the capital Technology Partners raises is allocated to the industry. Ehrenpreis waxes rhapsodic about Tesla's first car, the $109,000 Roadster, of which 1,200 were on order by the end of 2008; 937 had been sold by December 2009. "It makes a Prius look like a gas-guzzling hog and drives like a Ferrari!" he exults. A couple dozen of the brightly colored sports cars, which can travel 236 miles on a single charge, can sometimes be spotted whizzing silently along Silicon Valley's highways and streets, Musk's among them. The Roadster, says Ehrenpreis, shattered the belief that going green meant abandoning style; the next step is to roll out a more affordable Tesla sedan by 2011, and to raise capital for that through an initial public offering (IPO) of stock in the company, completed in June 2010.

Kleiner Perkins Caufield & Byers is one of Silicon Valley's most venerable venture firms; it has invested in most of the technology industry's landmark deals, now runs a $100 million "iFund" jointly with Apple in addition to its other portfolios, and has the same status in the venture capital universe that Goldman Sachs does on Wall Street east. But despite the motto on its website—"In Search of the Next Big Idea"—the firm passed up the chance to invest in Tesla. "All-electric cars probably aren't practical for a long time," argues Ray Lane, a partner at Kleiner Perkins and former president of Oracle Corp., the world's second-largest software company.

But Lane's resistance to the idea of investing in a next-generation kind of auto company didn't last long. Kleiner Perkins is now backing a more hybrid, less purist company, Fisker Automotive, launched by a designer who briefly worked for Tesla. "The Fisker cars are what I call a 'no-compromise' vehicle—beautiful and with a price point as well as features that will compare to a BMW," boasts Lane, who has a gray Fisker prototype in his garage at home that can run for fifty miles per battery charge. "To back these electric vehicle companies, you have to be as entrepreneurial within the venture world as the entrepreneur is within the corporate world—in other words, very, very willing to embrace risk." But, he quickly adds, Fisker was ready to build some seven thousand electric vehicles in 2010. "GM can't seem to produce one."

By being able to reconceive its role to include venture capital, Wall Street has proven itself, in the long run, more entrepreneurial than the Detroit-based automakers. It's not just venture capitalists that have spotted the potential of this new breed of automaker, however. Even with only a few dozen vehicles on the road, the fledgling green technology banking teams from Goldman Sachs, Morgan Stanley, Credit Suisse, and others were already making the trek to San Jose to check out Tesla and its rivals. So what if they are still guzzling capital faster than an SUV or Hummer can guzzle gasoline? Wall Street today doesn't need to be persuaded that it needs to be present from the very beginning if it is to capture all the business—and profits—it can. Sure enough, early in 2010, Tesla Motors filed to go public, with Goldman Sachs selected to lead four blue-chip underwriters; although the company had yet to generate a profit, it raised $266 million. As of July 2011, the stock hovered near $28 a share, a level the stock hit briefly on its first trading day.

How the Financing Life Cycle Works

There may be no better example of Wall Street's raison d'être than the role that venture capital—itself part of the money grid—plays in making entrepreneurial dreams a reality.

The same week that Lehman Brothers collapsed, the major figures of the venture capital community assembled at Microsoft's campus in Mountain View, California, a stone's throw from Sand Hill Road for the National Venture Capital Association's thirty-fifth anniversary. They listened to presentations by three carefully selected venture-backed companies: Tengion, a firm developing biotechnology to build new human organs from cells; Digital Signal Corp., which is honing 3-D facial recognition software that can be installed anywhere from airports to shopping malls; and Tesla Motors. Formalities over, the crowd escaped to the reception room to quaff Napa Valley wines and buzz excitedly about the meltdown under way on Wall Street east. One of the most visible of those present was former star technology banker Frank Quattrone, who had spent the 1990s steering one promising technology company after another through the financing process, from the first capital infusions to the initial public offering (collecting hefty fees for his firms, which included Morgan Stanley and Credit Suisse, along the way). He became the banker most closely associated with the dot-com boom, but years after it burst, he was back helping start-up technology companies raise capital.

That evening he was talking up his new quasi-banking venture Qatalyst, and debating the impact the turmoil on Wall Street proper would have on start-up businesses in Silicon Valley and his own firm's prospects. "He was very interested, feeling that this might pave the way for a revival of the old West Coast boutique investment bank, like the Four Horsemen," said one venture investor who was on the receiving end of his pitch that evening.

The Four Horsemen were four small to midsized investment banks—Hambrecht & Quist, Montgomery Securities, Robertson Stephens, and Alex. Brown—that individually and collectively carved out both a niche and a reputation for themselves as the go-to guys for entrepreneurs in need of finance, venture capitalists hoping to take their portfolio companies to the next level, and investors hoping to get in on the ground floor of the next great business idea. "We didn't go into this wanting to be Goldman Sachs; we knew we'd end up as a marginal player trying to compete with them on

ground that they owned, and that would be dangerous," recalls Bill Hambrecht, who founded the firm that bore his name and who now runs another boutique, W. R. Hambrecht & Co. "More than many of those larger East Coast firms, our model was very straightforward—we were there to help those companies move up the ladder to the next stage in their financial life cycle."

In 1981, the rest of the investment banking universe woke up to what was happening on the West Coast. "In a sixty-day period, we underwrote [the initial public offerings of stock in] Genentech, People's Express, and Apple," recalls Hambrecht. "I think we had sixty people in the firm; we made about $50 million that year and it changed everything." Hambrecht had attended college with the late Dick Fisher, then chairman of Morgan Stanley, who recognized what was brewing before the rest of the big Wall Street institutions. "He called me, then came to visit me, and told me, 'Okay, I want in on this business.' I asked him what companies interested him, and he mentioned Apple and a few others—he and his team had done their work and identified the best companies, not the biggest ones." Hambrecht & Quist would go on to co-manage multiple deals with Morgan Stanley, the two firms helping each other earn hundreds of millions of dollars more in fees apiece before Fisher retired and Hambrecht & Quist's partners decided to sell their firm to Chase Manhattan in 1999, at the peak of the dot-com market.

The names of the institutions that help Silicon Valley's most promising companies move from one stage of development to the next by providing capital directly or introducing the company to potential backers are likely to continue to change, but the process itself remains intact. The earlier it is in a company's life cycle, the more informal that process, as was the case with Google, now a corporate behemoth. One of the company's earliest supporters was David Cheriton, a Stanford professor who knew its founders, Sergey Brin and Larry Page. Cheriton also knew Andreas "Andy" Bechtolsheim, the cofounder of Sun Microsystems, and introduced him to the two would-be entrepreneurs at a gathering at his Palo Alto home. Bechtolsheim wrote Brin and Page a check for $100,000 on the spot even though the company hadn't yet been formed. He

followed that with another $100,000 when the first formal venture financing round occurred the next month.[12] (One firm that passed on Google was Bessemer Venture Partners; offered the chance to meet the "Google guys," tinkering in the garage of a friend's home, David Cowan asked if there was a way out of the house that would enable him to bypass the garage.)

In the space of those few weeks, the Google guys had rounded up another $760,000 in start-up funding after Bechtolsheim introduced them to John Doerr, one of Sun's earliest investors and at the time the lead investor at Kleiner Perkins. Where Doerr went, others eagerly followed: the imprimatur of Kleiner Perkins was as valuable as that of Good Housekeeping or Goldman Sachs. Doerr roped in Jeff Bezos (he had also provided start-up funding for Bezos's Amazon.com), who in turn brought along Amazon colleague Ram Shriram; all invested in the fledgling company long before it was clear that Google was going to become, well, Google. At the time, it was just another speculative "angel" investment, one of scores that each of these individuals undertook between 1998 and 2000. But by the time the IPO had been sold and Google's stock was trading on the public market, Bechtolsheim's $200,000 was worth $300 million or so.

A typical venture firm, such as Kleiner Perkins, raises and provides capital at the earliest stages of the financing life cycle. That capital comes from other buy-side players, such as college endowments, pension funds, and very wealthy individuals whom the general partners know and trust, often successful entrepreneurs such as Bechtolsheim and Bezos. Venture funds make most of their money from their share of the profits of their funds (usually 20 percent) but also collect a fee from their investor base in exchange for their services bringing together those investors with bleeding-edge investment ideas at their earliest (and most potentially profitable) stage of development. Without venture funds and their vast networks, how would Verizon's pension fund know that two bright young Stanford students were about to put together a company that within a decade would dominate the technology landscape? And how would Brin and Page have navigated the Wall

Street labyrinth in search of financing at such an early stage, while still working out of a friend's garage?

The next stage in the financing life cycle for venture-backed companies such as Google is a process that will allow those early backers to realize the value of their investment. People such as Doerr and Bechtolsheim, like everyone else on the buy side, don't want to keep their capital tied up in the same companies indefinitely; at some stage they want it back, along with a healthy return, in order to put it to work somewhere else and repeat the process. In other words, they want liquidity, just as any of those sixteenth-century merchants wanted to be able to sell part of his stake in the East Indian trading vessel long before it returned home with its hold stuffed with nutmeg, cinnamon, and silks so that he could provide his daughters with dowries.

By the time Google was ready to go public in the spring of 2004, its team didn't need any help from Bechtolsheim or Doerr in finding an investment bank willing to serve as an intermediary between Google and its future stockholders. Every investment bank in the United States, as well as an array of foreign competitors, wanted a piece of the action. Unlike all the dot-coms that had crashed and burned just months earlier, this technology company could point to real revenues, not just an ambitious business plan. It was a jewel, and every bonus-starved banker wanted a place on the list of underwriters—preferably as lead underwriter or, even better, the book runner, the guy in charge of deciding which equally excited mutual fund managers, brokers, and individual investors would win a few Google shares at the IPO price and who would get to pocket the bulk of the underwriting fee in compensation for all the aggravation. This would be a multibillion-dollar offering, and in a typical IPO, the underwriters collectively could pocket as much as 7 percent of the proceeds as their fee.

Every banking team in the world began to chase the deal, and they all took it very seriously indeed. Morgan Stanley opened up a Silicon Valley war room, complete with a team of top bankers and analysts preparing pitch books and rehearsing answers to questions they expected to get from Lise Buyer, then Google's chief financial

officer, and the other Google execs who would select the winners. "It was just like a presidential election campaign," recalls Hambrecht. Two weeks before the "bake-off" was scheduled to take place at the Palo Alto offices of Google's law firm, Wilson, Sonsini, Goodrich, & Rosati, pitting the finalists against each other, Morgan Stanley's team hired the key analyst that Hambrecht had assigned to prepare his own firm's pitch for the deal. "They wanted to find out what we were doing," Hambrecht says, shrugging. "All's fair in love and war."

And this was war, make no mistake about it. On a Saturday afternoon in early April, the finalists were scheduled to appear, one at a time, to make the final pitch to Google executives and board members, each explaining (with the aid of thick pitch books stuffed full of charts, diagrams, and other propaganda) why they were the only guys for the job. The Google folks knew what they were in for. Buyer had helped prepare pitch books herself in a previous life as a top technology analyst. Aware of the other tricks that Wall Streeters liked to play, she instructed the top bankers to stay home, decreeing that only the middle-ranking people who would actually do the grunt work on the deal should show up. (Few abided by that rule.) She also told them to be creative. "We wanted to be sure we'd be working with bankers who got our corporate culture, so I guess we kind of opened the door to a lot of the silliness that followed," she said.

One banking team brought beer, apparently assuming that a freewheeling culture was synonymous with the liberal consumption of alcohol. Another tried to design a PowerPoint pitch incorporating Google's own search engine, which would spit out the firm's name when asked, "What is the best bank to underwrite Google's IPO?" (The technical challenge proved impossible, and the banking team resorted to a paper version of the same pitch.) Citigroup's technology bankers designed laminated place mats that spelled out the bank's achievements and creative strategies for marketing Google to the public, using Google-like design elements and layout. The place mats probably came in useful for the pièce de résistance. The banking team from Goldman Sachs, taking to

heart Buyer's quip that, "given that we're all here on a Saturday afternoon, you can damn well bring me dessert," and learning through their own research that Brin and Page loved chocolate, ordered up a big chocolate cake, emblazoned with the Google logo, to bring to the pitch meeting. Stunts like that have been known to work, as Lisa Carnoy, who is now global capital markets co-head at Bank of America, knows from her days co-managing the same group at Merrill Lynch & Co. Pulling together a pitch book for the investment bank's presentation to Lululemon, a yoga clothing retailer seeking to go public, Carnoy included details of the favorite yoga positions of each member of the banking team in hopes of showing just how much the bankers understood their potential client's business. "They got a kick out of that and we got the deal," she recalled.

Winning an IPO is one matter; completing it to the satisfaction of all parties is something else altogether. However crucial the role played by Wall Street in bringing together and reconciling the competing interests of the buy side and the sell side, there is usually one group that feels it has given up too much in the process. A typical IPO investor, for instance, wants the largest allocation possible of a hot new issue. Many of those investors are also investment bank clients; they execute buy and sell orders and generate trading fees for Wall Street institutions year-round and aren't shy about telling the investment banks what they expect them to deliver in return. Fidelity, back in the days when it routed more than half of its immense trading activity through Wall Street trading desks, routinely threatened to "cut the wire" and trade with a particular investment bank's rivals if it didn't get an allocation twice that of its nearest competitor for an enticing IPO. The investment bank usually obliged.[13]

To make the buy side happy, the new stock should be priced at a level that will allow it to rise in value—preferably by 20 percent or more—in the days immediately following the IPO. That gives any mutual fund manager the chance to sell some of his shares at a quick profit—and can mean a big boost in trading revenues for the investment bank as trading volume in the newly public stock shoots

higher. When Netscape went public in 1995 at $28 a share, it posted its first trade at $71. Those watching the electronic screens were convinced it was a typographical error or that they were hallucinating. An entrepreneur watching that kind of drama, however, is well aware that he may have just lost millions of dollars of new capital for his company and is left wondering whether Wall Street has just ripped him off. "Everyone was angry about that, and very vocal about" what they viewed as giving up that much in potential proceeds, says Buyer.

Google tried to ensure that it would capture as much of the proceeds as possible for itself and its backers. In fact, while the deal itself turned out to be messier and less profitable than anyone had hoped, it did at least leave all three parties—the buy side, the investment bankers, and the company itself—feeling equally dissatisfied. Morgan Stanley and Credit Suisse were told they had won the coveted co-lead-underwriting spots but that they would have to use Hambrecht's new method of capital matchmaking, a kind of auction that forces would-be buyers to bid against each other for the stock, disclosing the maximum price they will pay. That approach was anathema to both bankers and the buy side: it not only involves a much smaller fee for the underwriters (about 2 percent of the proceeds rather than the traditional 6 percent or 7 percent) but also in theory eliminates the possibility of a first-day pop in the price of the newly public company of the kind that investors cherish but that issuers such as Google had learned to loathe. Hambrecht's new firm, W. R. Hambrecht & Co., which had devised the auction methodology, won a co-manager slot due solely to Brin and Page's fascination with the auction idea rather than his four-page stapled pitch, which Buyer rated the worst she'd ever seen.

For their part, potential buyers were disgruntled at being asked to relinquish their traditional instant profit. Hambrecht remained unfazed. The auction process, he says, "means that Wall Street is really fulfilling its role as the intermediary because the proceeds are going to the company, not as instant, nearly risk-free returns to the bankers or investors who've owned the stock less than seventy-two

hours." The rock-bottom fee took a toll on the process, banking analysts would later argue. Merrill Lynch walked away from the underwriting syndicate outright, unwilling to do all the work for what it saw as a skimpy return. The remaining underwriters later confessed to being reluctant to battle as ferociously as they might have done to combat buyer apathy, given the low fees. Buyers lowballed the deal, responding to the process and the deteriorating climate for technology stocks. Google had to settle for a price of $85 a share, instead of the $135 it had hoped to make from the deal.

The Troubled Heart of Wall Street

The process of underwriting an IPO or raising other kinds of capital for companies such as Google and providing exit strategies for their venture backers remains one of the core "utility" functions of Wall Street's big investment banks. "It's really not all that different today from the way it was back in the 1960s, when I wrote my first-ever case study about the IPO process," says Samuel Hayes, professor emeritus at Harvard Business School. Only the names of the issuers and the underwriters are different, while the dollar amounts are larger. But as the Google transaction illustrates, the relationships between Wall Street institutions and the two groups on either end of the capital exchange transaction that develop when a company goes public or otherwise raises new debt or equity capital aren't always smooth and straightforward. On the sell side, corporate clients such as Google don't always feel that their investment bankers are looking out for their best interests. Meanwhile, parts of the buy side—the investors—are just as skeptical.

The first part of the problem—the increasingly bumpy relationship between the investment bank and its corporate clients—Hayes attributes to changes on Wall Street itself. The mergers that have taken place over the last twenty years—all of the Four Horsemen were absorbed by national institutions, most of which in turn became part of still more massive financial behemoths—mean

that doing the kind of smaller deal that is characteristic of what most companies need in the earliest days of their existence isn't cost-effective. Venture capital investors are well aware of this trend, and it worries them. "Unless I have another potential Google, these guys don't want to know," says one Silicon Valley venture capitalist bitterly. "They want the sure thing, the big deal that is going to be able to make a visible difference to their own profits at the end of the quarter. They are more interested in that than in building relationships with corporate clients that might generate a stream of fees over the years. They have betrayed our trust." He points to Goldman Sachs, which shuttered its Sand Hill Road outpost (in a building it had shared with archrival Morgan Stanley) a few years after the tech bubble burst. "They'll fly people in for things they consider important, but there aren't as many people competing to serve this space, which means that all the companies that we are starting to fund today are going to have a much harder time in the later stages of their corporate lives when it comes to getting financing."

This venture investor predicts that a greater number of venture-backed companies will wither on the vine, unable to get financing simply because of their size relative to that of the investment banks. That, he argues, may not augur well for the future of both entrepreneurial energy and Wall Street. Will some prospective entrepreneurs be deterred or some promising companies derailed? And what happens if Wall Street turns its back on its core function of helping promising businesses realize that promise by accessing capital? "We play our role; we want Wall Street to play theirs."

For now, at least, the venture industry is keeping its part of the tacit bargain and continuing to invest billions of dollars a year in start-up companies. Despite the market chaos, venture funds still want to back the companies that they believe have the potential to become next-generation versions of Genentech, Google, or Amazon. These days those companies will range from start-ups offering innovative ideas on managing power grids more efficiently to businesses based on new medical devices. But by 2009, the signals were becoming more mixed. Wall Street's recent aversion to doing

what it saw as small-scale underwriting deals had remained, and had been exacerbated by the general chaos as banks focused on their own internal restructuring. That forced some venture companies to direct as much as 40 percent of their investment funds in 2009 toward existing, relatively mature companies still languishing in their portfolios and unable to find an exit.[14] In a normal year, says Jim Feuille, a general partner at Crosslink Capital, his venture capital firm invests in eight or nine new businesses. By late October 2009, they had selected only three new companies in which to invest, in order to preserve enough capital to be able to continue supporting those older businesses. The National Venture Capital Association reported that the same trend was being seen across the industry: by the third quarter of 2009 only 13 percent of all venture capital investment dollars were directed to first-time companies, the lowest percentage on record. While a surge in IPOs in the first half of 2011 revived confidence somewhat, some still fret about Wall Street's willingness to stick around in bumpier times.

This kind of breakdown in the relationship between Wall Street, as represented by investment bankers, and its corporate clients isn't confined to Silicon Valley—nor, as I'll explain later in the book, is the breakdown restricted to one part of the money grid. The relationship between Wall Street and its partners on both the buy and sell sides has been under threat for more than a decade, as Wall Street drifted further and further away from its core utility function and those clients generated a decreasing proportion of its revenues and profits.

From Gatekeeper to Casino Croupier?

Harvard Business School's Sam Hayes studied the breakdown in the relationship between Wall Street and its corporate clients in real time and knows whereof he speaks. He holds the Jacob H. Schiff Chair in Investment Banking as a professor emeritus and has studied Wall Street from the perspective of a scholar (he has published

seven books and countless research papers and other articles about various aspects of Wall Street), a consultant (to the Justice Department, the Treasury Department, and the Securities and Exchange Commission, as well as many businesses), and even a participant (he chairs the investment committee at his alma mater and is a former chairman of the Eaton Vance family of mutual funds, making him a member of the buy side, while his role as a member of the advisory board of brokerage firm Edward Jones puts him on the sell side). When in 1970 he began scrutinizing the way Wall Street worked, it was performing its intermediary function adeptly; the relationships with clients, he says, were true long-term ties of importance to both parties. When a CEO wanted to sell bonds, raise new capital through a stock issue, or mull over other strategic issues, he'd pick up the phone and call his banker. That banker would be the same person, or at least someone at the same firm, year after year.

But Hayes soon began to detect signs that those relationships were crumbling, as they came under siege from both sides throughout the 1970s. A new breed of CEOs and chief financial officers with MBA degrees felt better equipped to pit one Wall Street firm against another in search of a way to cut financing costs. Wall Street firms were quite eager to poach their rivals' investment banking clients, adding fuel to the fire. To both groups, this breakdown seemed logical and even beneficial—why shouldn't corporations shop around for the best deal and investment banks compete to offer that deal? By 1978, Institutional Investor magazine had stopped publishing the annual "Who's with Whom" list documenting which firms "banked" which corporate clients. "Clients didn't like being labeled as 'belonging' to Kuhn Loeb," Hayes recalls.

The turning point came a year later when IBM wanted to add Salomon Brothers as a co–lead underwriter to a bond sale it was planning. When the company informed its traditional bankers at Morgan Stanley of its wish to include Salomon because of the latter's growing importance in the bond markets, Morgan Stanley refused to share the spotlight. (At the time, Morgan Stanley, in an

attempt to emphasize how exclusive it was in the clients it accepted, even insisted on using a special typeface in the newspaper "tombstone" ads announcing deals it had done.) Instead of backing away from the idea, as Morgan bankers had expected, IBM awarded the whole deal to Salomon Brothers, shutting out Morgan Stanley altogether. It wasn't until 1984, when Morgan Stanley agreed to share the lead underwriting role for Apple with Hambrecht & Quist, that the blue-chip New York firm conceded that it would have to relinquish part of the limelight on occasion in order to participate at all in the deals it wanted to do.

If IBM's decision to put its foot down was the turning point in the relationship between Wall Street and the sell side, the tipping point in ties between the Street and its buy-side clients came in 1995, when Netscape went public with the assistance of several leading investment banks. The transaction certainly was part of Wall Street's core function—the underwriters were raising money for a corporate client—but the company in question had a far riskier and less established business model than those that bankers were accustomed to introducing to the buy side. With Netscape, says Lou Gelman*, a former Morgan Stanley banker involved in the IPO, Wall Street was asking its buy-side clients to adopt a completely different approach to investing. Netscape wasn't earning a profit, and its business model was untested, relying on the then-new phenomenon of the Internet. "Until Netscape came along, Wall Street used to say a company had to have two years of operating profits in order to go public," Gelman says. But Morgan Stanley badly wanted a piece of what promised to be a very hot IPO. "Suddenly our top guys were tossing their own rules out the window in order to get this business."

Above all, the Netscape IPO opened the door to speculation as an investment strategy. It was now in Wall Street's financial interest to encourage its buy-side clients to toss away their concerns about investing in a relatively risky business. "We went from being a gatekeeper to [being] a croupier," says Gelman. Until that time, he argues, Wall Street had served its buy-side clients by helping them preserve and protect their wealth. Now the ethos seemed to have

changed; Wall Street was becoming a casino, a place where people could create wealth rapidly by speculating. "It was with the Netscape IPO that the conviction we have today—that it's actually possible to get rich in a day by owning the right stock—took root," Gelman says. "It's corrupting."

Not only that, but for several years it was also exciting and dramatic; that drama would help swell Wall Street's own coffers as hundreds of Internet companies followed Netscape's lead and paid their 7 percent underwriting fee to go public. It all followed the success of the Netscape underwriting team, which, after overseeing the production of an IPO prospectus containing twenty-plus pages of risk factors, took the fledgling Internet company's management team on the road to drum up buying interest. The target stock price crept slowly higher, to $12 per share and onward, as public awareness grew during that "road show." The battle to acquire stock in the deal ended up bringing Wall Street and Silicon Valley to Main Street's attention; both captured the imagination of ordinary investors who until then had never had a brokerage account. One caller to Netscape's headquarters asked what the IPO signified. "Essentially that means our company will be trading a certain number of shares on the stock market, which will raise capital so we can expand our business," the operator informed him. "What's the stock market?" the caller inquired. Another caller had heard people talking about the deal in the grocery store and wanted more information. A third threatened to report Netscape to the San Jose police for "insider trading" when he wasn't allotted shares at the IPO price of $28 apiece. It's not surprising he was unhappy: the stock soared as high as $75 in its first trading day, before closing at $58 a share.

The external exuberance wasn't always matched inside Morgan Stanley itself, even after the deal turned into a runaway success story. "Some of us pushed back, but the argument came down to the reputation of our franchise against the potential revenue," says Gelman today. "Were we going to be the firm that doesn't do early-stage IPOs, when this is what the public wants to buy? No one, it turned out, was willing to walk away and leave that to our rivals."

By the time the dot-com bubble was fully inflated, Gelman was convinced that the capital-raising process had undergone a fundamental change. “We weren’t there to provide companies with the best long-term sources of capital to grow with; we were doing this to help our investor clients get richer faster.” In his view, Wall Street had abandoned both of its core constituencies in pursuit of its own self-interest.

That approach gained momentum as the years passed, and extended into a variety of products, including higher-risk corporate bonds and collateralized debt obligations (CDOs), the bundles of mortgages (including those issued to subprime borrowers) that had been repackaged in the form of marketable securities. Caveat emptor, Wall Street declared—buyer beware. “Eighteen or twenty years ago, when someone [on Wall Street] showed us a bad product, we went crazy; we’d tell them, ‘Don’t ever show us that again,’ ” recalls Scott Amero, a portfolio manager at BlackRock, a major buy-side asset management firm. “At first we took the time to explain why something was a bad product, why it was risky or poorly designed.” But eventually Amero found it impossible to provide that kind of detailed feedback: either the relationships weren’t strong enough to permit it or the banker wasn’t in a position to do anything about BlackRock’s concerns, especially since there were other willing buyers. All Amero could do was go on a buyer’s strike. In 2009, Larry Fink, one of BlackRock’s founders and its chairman and CEO, gave voice to his fury with Wall Street for abandoning its traditional role as gatekeeper that took care to funnel only valid and viable products to the buy side. In the past, Fink told the Financial Times, firms such as BlackRock “relied on Wall Street to be the safety guards to the capital markets,” winnowing out the poor-quality deals. Now, he added angrily, it seemed as if it was up to his firm and other buy-side institutions to protect the integrity of the parts of the market.[15]

The Core Function Becomes a Sideshow

The IPO market may be one of the best examples of Wall Street's core function at work, funneling capital from those who have it to those who need it. But Wall Street saw underwriting IPOs as less and less attractive with each year that passed. Most transactions were far smaller than either Netscape or Google, and the amount of work the investment bank had to do in order to drum up investor interest in a previously unknown company could be time-consuming. When that company planned to raise only $15 million or so, the fees were small. But being willing to work on an IPO was what a bank had to do in an era where relationships alone were not enough to win business. Some, such as Morgan Stanley's Dick Fisher, realized that technology companies weren't going to generate a lot of banking fees in the future. They didn't need much new equity after an IPO, typically, and almost never raised debt capital, since they didn't have the kind of fixed assets that bond buyers like to see. Unless the company decided to make acquisitions, the IPO fee might be the only banking revenue the underwriter ever earned. "Fisher told me he knew [companies such as Adobe and Apple] weren't going to be good investment banking clients," says Hambrecht. "He was right; Adobe had a $10 million IPO and then never raised another dime on Wall Street."

But Fisher's ultimate goal was to capture a different kind of business and a more secure stream of fee income for Morgan Stanley: he wanted to woo the newly wealthy executives as clients for Morgan Stanley's private banking team. "Sure enough, Morgan Stanley ended up managing about 90 percent of the wealth created in the Apple IPO, while Goldman Sachs did the same for their Microsoft millionaires," says Hambrecht. And when the $4.4 billion initial public offering of stock in UPS closed in November 1996, Morgan Stanley saw its $50.5 million share of the $191.5 million in fees paid by "Big Brown" to the thirty-five-member Wall Street underwriting syndicate as just the tip of the iceberg.[16] That evening, when UPS's top brass sat down to celebrate the first day of trading in their new stock (and its 30 percent pop in value), they were sharing their prime rib not only with the bankers who had sold the stock but also with the Morgan Stanley wealth managers summoned

to woo them as clients for that side of the company's business. Yes, Wall Street was changing.

Some of those who felt as if the new Wall Street was leaving them behind as it drifted further away from its core function came from within the ranks of Wall Street itself. While one group of Wall Street bankers focused on helping companies raise new capital, another specialized in advising corporate clients on making a different kind of match: negotiating a merger with or acquisition of another business. Fees on these transactions may be a smaller percentage (from 1 percent to 3 percent) of the value of the deal, depending on the complexity and the players—but the deal sizes can be large. And a satisfied client can earn a banking team a series of fees year after year, as a business grows through acquisitions. JDS Uniphase, an optical networking company, forked over $30 billion in stock for big-ticket acquisitions in just a few years, each of which generated hefty deal fees—mostly in cash—for the matchmakers who helped orchestrate them.[17]

At any rate, this part of Wall Street tended to see itself as an elite group. Other members of their firms underwrote stock and bond offerings, handled sales and trading, or devised structured products such as CDOs and might generate high fees when their part of the business enjoyed its moment in the sun. But the mergers and acquisitions (M&A) advisory business, in their eyes, was the heart of what Wall Street was really about. "In my mind, the really sharp minds on Wall Street are not doing IPOs or debt financings; they're doing strategic stuff like M&A advisory work," says Mike Donnelly* bluntly. Donnelly, who lost his own job in the wake of the collapse of his firm, hasn't lost his awe for those he considers to be Wall Street artists. "Someone who is really great at this has a knowledge of the business, the industry and the company and the strategic issues that lie ahead. He has the technical knowledge, he knows the latest twists and turns in accounting rules and the law. He has experience and is never taken by surprise because he knows the kind of odd things that can happen," explains Donnelly. "And they can present everything to a board in a lucid and compelling way. I suppose they're a bit like a Pied Piper: people who hear them will

end up following them anywhere. It's incredibly hard to find someone like that, and that's why they are so valuable."

Robert Greenhill, Morgan Stanley's president and Fisher's heir apparent back in 1992, has always been that kind of banker. Flying his own Cessna from one client meeting to the next, he and his team had propelled the firm to the coveted top spot in the league table rankings. (These widely scrutinized lists, published quarterly by data groups such as Dealogic LLC and Thomson Reuters, told the world which investment bank had underwritten the most deals in any specific area imaginable; the battle for league table credit and the bragging rights that went along with a top-three finish was fierce and remains so today.) Alas, merger volumes were down overall that year, and John Mack—whose own background was in sales and trading, the heart of the underwriting function—ended up elbowing Greenhill out of his way. Deposed as president in early 1993, Greenhill resigned shortly after, first joining Sandy Weill as the latter began to construct the behemoth that would become Citigroup and later founding his own boutique advisory firm. He left behind him what became known as the "Greenhill gap"—there was no one who was his equal as a rainmaker for the firm.[18]

To Gelman, the former Morgan Stanley banker, Greenhill's departure symbolized the final transition of power from the long-term strategic thinking characteristic of an M&A advisor to the emphasis on speculation and short-term profit maximization symbolized by the rising power of the trading desks and their chiefs within the power structure of many investment banks. "By the time Netscape came along, serving investors who were speculating and trading like crazy—and trading for our own account—had become what it was all about," he says. "Even in the IPO business, what had been a craft became an assembly line."

But by then, there was no way for Wall Street's investment banks to become purists, even when it came to fulfilling their gatekeeper role. Too much had changed in the world around them, and their responses to those changes had produced a series of unanticipated consequences. Long before the Netscape IPO was a gleam in the eye of the company's venture capital backers, it had become clear to

investment bank CEOs that relying on the basic gatekeeping functions of yore was never going to generate enough profit to keep their ever-expanding empires afloat.

CHAPTER 2

Building Better—and More Profitable—Mousetraps

Long before the dawn of the twenty-first century, it was clear to Wall Street's leading investment banks that while being a superstar at raising capital or negotiating mergers might earn them kudos, it wouldn't keep their shareholders happy in normal or slow market environments. These publicly traded entities needed to deliver reliable, consistent, and ever-increasing profits to their investors, whether or not the cyclical financial markets cooperated. Fees tied to the process of raising capital for clients—which was, in its turn, dependent on those financial market cycles—weren't going to be enough to keep shareholders happy. The future of Wall Street's biggest institutions lay not simply in helping Main Street clients navigate the liquid and transparent stock and bond markets but in generating newer and more exotic proprietary products.

The ugly end to the dot-com boom in early 2000 drove that message home to Wall Street decision makers like nothing else had done. They had spent the waning years of the twentieth century chasing the kind of fees that had been the bread and butter of Wall Street: taking start-up technology companies public, raising both debt and equity for the likes of WorldCom and AT&T Wireless, and pocketing merger advisory fees by helping companies such as Cisco and JDS Uniphase snap up innovative young companies. At least some of those who were part of that boom look back on it now with a degree of wistful nostalgia as the last golden age for the classic investment banker. "It was a period when we did what we were good at, more efficiently than ever before, and made more money for ourselves than ever before," says Larry McInnes*, a veteran technology and telecommunications banker.

Shareholders were happy; the average brokerage firm reported a 27.3 percent return on equity in 1999.[1] Goldman Sachs, which hadn't even had an investment banking office in Silicon Valley itself until that year, nevertheless managed to grab a commanding lead in technology stock underwriting, helping it capture a return on equity of 34.2 percent and making the firm—yet again—the envy of all the other chief financial officers on Wall Street. But that happiness could endure only as long as the market bubble kept inflating. Profitability on that scale came from making Wall Street's core process work overtime. After Netscape changed the game, Wall Street, eager to capture its share of the speculative frenzy in the shape of investment banking fees, was happy to fuel that frenzy by underwriting initial public stock offerings for increasingly risky companies, some of which had been in existence for just months and had no revenues, much less profits, to offer their investors. Goldman Sachs led the offering for Webvan, a grocery delivery service that rapidly closed its doors, while Merrill Lynch brought Pets.com to market; that company shut down ten months after the IPO. But Wall Street's priority was keeping its own shareholders content; as transactions became more speculative and riskier for investors, they became increasingly lucrative for the investment banks.

In 1995, the fee per transaction (equity and debt underwriting as well as advisory fees) on Wall Street hovered around $1.19 million; it hit $1.48 million in 1998, $1.81 million the next year, and a high of $2.03 million in 2000.[2] The average Wall Street bonus nearly doubled between 1998 and 2000, topping $100,000 for the first time.[3] Goldman Sachs alone had pocketed $24.5 billion in fees for underwriting sixty-three IPOs during 2000. By the end of that year, two-thirds of all IPOs were trading below the price at which the stock had first been issued. Investment banks were not going to give back any of their fees, however.

Still, with the classic financing process in a cyclical slump and the average ROE for investment banks and brokerages plunging to between 12 percent and 13 percent in 2001 and 2002, it was time for Wall Street to play the card it had kept stashed up its sleeve for

years. The fact was that Wall Street firms no longer needed to rely purely on the fees they earned for overseeing processes such as underwriting, sales and trading, or advising on mergers. These intermediary functions were profitable only when they could be done in tremendous volumes, as had happened at the height of the dot-com boom. The longer the slump that began in 2000 lasted, the more Wall Street needed to find an alternative source of revenue, preferably one with a higher profit margin.

Wall Street couldn't survive without fees, as veteran banking analyst Mike Mayo pointed out in the first round of hearings convened by the Financial Crisis Inquiry Commission (FCIC). Fees from Wall Street activities, Mayo noted, had generated no more than about 20 percent of bank revenues from the early 1950s right up until the early 1980s. But as other sources of revenue slid and banks found ways to create, package, and sell more exotic securities, that proportion rose—by the late 1990s, banks were earning some 40 percent of their revenues from fees. The answer, it became clear, was to develop structured products: the more complex the better, since the more sophisticated investment and risk management products commanded the highest fees from their clients.

As Federal Reserve monetary policy makers addressed the recession of 2000–2002 by slashing interest rates to the lowest levels most Wall Street bankers had seen in their lives, it made sense that many of these new products would be tied to two markets that are not only the country's largest but also closely linked to interest rates: the debt market and the housing market. Lower interest rates drove borrowing costs down for everyone, from the biggest leveraged buyout fund to the most cash-strapped home buyer. Not surprisingly, the level of borrowing skyrocketed, as did a host of new Wall Street debt products, from the relatively straightforward corporate bonds to leveraged loans and the now-infamous collateralized debt obligations (CDOs).

By 2005, the CDO had steered Wall Street back into extremely profitable territory. The focus on products (in the shape of CDOs) helped profitability per transaction jump back to $1.54 million and

then to $1.91 million in 2006, by which time the CDO market was worth a whopping $2 trillion, according to research firm Celent. (Estimates are that Wall Street investment banks and other participants in the mortgage boom had pocketed the same amount in fees for originating, packaging, and repackaging the mortgage-backed securities in those CDOs during the five years from 2003 to 2008.) Wall Street was hooked, this time on a product—the CDO—rather than on a process such as IPO underwriting.

As profitability zoomed, so did the risk. As one unnamed subprime lender in California recounted, "The sales guys from the Street would come and talk to you and hype you up. They would try to get you to do something. From Monday to Thursday you would make the loans.... By Friday your mistake would be on the marketplace" in the form of a new CDO.[4] The subprime lender (a firm such as Angelo Mozilo's Countrywide, for instance) pocketed an origination fee for making the loans; the Wall Street institution begging for the raw material to turn into CDOs collected the fees for gathering the loans together, repackaging them, and selling them. The quantitative analysts on Wall Street, who used mathematical or statistical markets to analyze the financial markets and develop new trading and investment strategies and tactics (these "quants" would become known as the Street's rocket scientists), began pushing the boundaries of the possible still further. As margins on CDOs began to dip, they first sought to create CDO-squared products (made up not of packages of mortgage-backed bonds but of chunks of CDOs) and even CDO-cubed structures (made up of pieces of a few CDO-squared products in a different combination). These variants weren't even composed of real assets but were "synthetic" securities, built of derivatives designed to mimic what the real assets would do.

Ultimately, Wall Street came to rely on these exotic securities for its profits. At the end of the day, there are a finite number of blue-chip companies that need Wall Street's help to raise capital or complete a merger deal. Persuading any one of those to do one extra deal a year is time-consuming and the odds of success are low, as any Wall Street veteran will admit; corporate deal makers are

well aware of the many studies showing that most mergers don't deliver the promised operational or financial benefits. Without a clutch of blockbuster deals—a few IPOs like that of Google, a series of multibillion-dollar takeovers on which to earn advisory fees—it was going to be hard to earn the kind of profit margins investors wanted. Wall Street needed help, and one of the places it found it was in the development of a new kind of deal machine, based on proprietary products. If the deal machine faltered, investment bankers knew, so would profit margins—and that just wasn't acceptable.

For all its fascination with correlations—market relationships, such as that between the price of crude oil and the value of oil and gas drilling companies, for instance—Wall Street seemed oblivious to one of the most significant correlations of all. Whenever its own fee income spiked to unusually high levels and its ROE levels surged well above average levels (by some calculations, around 15 percent), disaster seemed to follow. That had happened in 1999 and 2000. In 2006, the average ROE of the investment banks hit an average 23.3 percent, with Goldman Sachs again leading the pack with 33.3 percent. But Larry Sonsini, the Silicon Valley lawyer whose firm advises about four hundred public companies and thirty-five hundred privately held businesses, was watching with growing anxiety. "Month by month, year by year, I saw one investment bank after another drifting further and further away from their knitting, investing more and more in products rather than services," he says. Even the rhetoric changed, he observes. Instead of talking about Wall Street's role in the economy, the bankers he knew began to emphasize their role as profit-making businesses with no overarching economic mission. "They didn't even realize that they were moving outside the boundaries of what they had traditionally done; much less ask if it was a good idea for themselves, let alone the broader system. And as it turned out, they screwed up; Wall Street didn't understand what they were doing well enough to manage the risk associated with it. They felt they needed this business, and now we're all paying the price."

Even those who served as the earliest architects of this new Wall

Street didn't fully recognize the transformation they were helping to orchestrate. At Salomon Brothers, Lewis Ranieri knew that securitizing mortgages just made good sense for all concerned, from homeowners to investors—and certainly for Wall Street. He didn't envision the advent of collateralized debt obligations (also known as CDOs), much less CDOs squared or synthetic CDOs based on credit derivatives. He certainly didn't conceive of how those later innovations would transform an idea that made sense for all parties and that served a need for Wall Street's client base, into little more than a casino. As he later admitted in an interview with Fortune magazine, "I wasn't out to invent the biggest floating craps game of all time, but that's what happened."

Certainly, no one recognized the implications of the changes within Wall Street institutions that accompanied the shift in focus. The emphasis on products, rather than services, meant that relationships with clients became slightly less important with every month that passed. It took years, but by the end of the transition, few people were surprised when Goldman Sachs's CEO Lloyd Blankfein implied during his testimony on the Hill and to FCIC panelists that the firm's clients needed to do their own due diligence. Clients were on their way to becoming little more than counterparties. The inflection point had come and gone.

Mayday, Mayday, Mayday!

Wall Street's obsession with products and product innovation as a recipe for profits has roots more than thirty years old. May 1, 1975, has gone down in the history of the Street as "Mayday," the date the Securities and Exchange Commission had dictated would mark the end of fixed trading commissions in the stock market. Overnight, Wall Street's comfortable existence was shaken; its long-standing business model was turned upside down.

Until then, investors had been forking over 40 or 50 cents a share to place a buy or sell order for stock through their broker. "I was a big producer, because I'd do one trade in connection with a deal."

recalled the late Fred Joseph, former CEO of Drexel Burnham (itself a victim of product-related risk-taking in the form of junk bonds), who went on to cofound a boutique investment bank, Morgan Joseph. "I could make a $500,000 fee without discussing it with the client" simply because the commission was fixed. Those fees, many paid by big institutional investors such as Fidelity and Capital Research and Management, earned massive profits for those who did nothing but execute the trades. Jimmy Cayne, then a rising broker at Bear Stearns (and later its CEO and chairman), pocketed up to $900,000 a year at a time when Bear's partners earned only $20,000 plus a share in whatever profits the firm made each year.[5] "Oh, that was a wonderful cushion," recalled Joseph. Those profits, he explained, helped subsidize all kinds of other businesses that were vital to Wall Street's core function but that didn't make much money in their own right, such as research.

When regulators dismantled the fixed commission structure, they weren't thinking much about the unexpected consequences that might follow. Their focus instead was on the rebound in trading volumes that took place as the bear market of the early and mid-1970s loosened its grip. A pricing system that seemed reasonable when the average daily trading volume in a stock might be a few hundred shares looked like Wall Street getting rich at the investor's expense when volumes climbed. After all, it didn't cost a brokerage firm ten times as much to trade a thousand shares as it did to buy or sell a hundred shares of stock, in terms of the salaries paid to staff on the New York Stock Exchange, telecommunications costs, and other forms of overhead. Commissions of 40 cents a share were simply too costly for Wall Street's buy-side clients—the investors—to sustain, and the SEC decided that the intermediaries should have to negotiate their fees with their clients, competing against each other to offer the best deal. At Goldman Sachs, bankers recall they expected those transaction fees to fall 10 percent or so during the first few months of the new pricing regime. It was one of the few occasions when Goldman Sachs would be proven dead wrong. By the end of Mayday itself, the first day of the new trading fee regime, Wall Street's largest and (until now) most profitable customers had

used their clout to negotiate trading costs that were half what they had been the previous day. The trend continued. By the 1990s, trades that had once cost dollars to execute could be done for pennies; even the smallest individual investors were benefiting as discount online brokerages offered rock-bottom trading fees to win their business.

Initially, the end of fixed commissions won the moniker Mayday simply because of the date the new system began—the traditional May Day, celebrated for centuries as the beginning of spring. But perhaps the selection of a word that doubles as a radio communications signal for a life-threatening emergency wasn't all that coincidental. Michael LaBranche, now head of one of the New York Stock Exchange's firms of specialists, recalls people walking around the trading floor lamenting the changes and proclaiming it was the end of their business.[6] In a way, it would prove to be just that. Even those firms who had supported it, such as Merrill Lynch (which hoped to use negotiated commissions as a way to nab a larger share of the trading business), couldn't have anticipated the long-term consequences, in particular the scramble to replace the now-vanished cushion of earnings.

Wall Street's Mayday "changed the whole nature of Wall Street; what we did and who we were," argues Wilbur Ross, a financier and private equity investor who at the time worked in an institutional brokerage that specialized in research. No longer did the large and lucrative trades by big institutions help investment banks and brokerages subsidize less profitable but systemically important businesses, such as executing trades for individual investors and providing investment research. "Research suddenly had no value in its own right and wasn't being subsidized," Ross contends. "So the clever people on the Street said, 'Okay, we'll use these smart and well-paid people to bring in investment banking business.' " That led directly to one of the Wall Street scandals of the last decade, the one that pointed out just how wide the gulf had grown between the Street and the investors who had previously relied on firms such as Merrill Lynch not only to execute their trades but to give them advice.

Henry Blodget, the former hotshot Internet analyst, had done a very good job picking winners for Oppenheimer's investment clients, suggesting that they snap up shares in Amazon.com when the online retailer was trading at about half of his price target of $400; it breezed through that level only weeks later. That forecast grabbed the attention of Merrill Lynch, which recruited him to make research calls that would be just as lucrative for their clients. But if Blodget was good (in the short term) at picking dot-com winners, he proved great at raking in investment banking fees and being a cheerleader for the speculative Internet stocks. Even when their prospects soured, Blodget remained publicly upbeat. After the bubble burst, regulators began to question just why supposedly smart people had advocated that the rest of us do stupid things. They discovered that Blodget had sent internal e-mails to Merrill Lynch colleagues, griping about having to talk bullishly about overvalued and risky stocks just to help Merrill land investment banking deals. Blodget later forked over $2 million in fines (Merrill itself paid $100 million) and was barred from the industry for life, but he was far from the worst offender. And to this day, no one has figured out how to make independent and substantive investment research a paying proposition for a Wall Street firm.

For his part, Wilbur Ross simply shifted gears, forging a career first as a turnaround specialist and investor in distressed assets at Rothschild Investments, then launching his own specialized buyout firm in 2000. In his new position, Ross rarely had to worry about dealing with the pressures that Mayday had unleashed—particularly the push to produce a constant stream of high-margin new products that could help (temporarily, at least) fill the void left by the disappearance of fixed commissions. But he was aware of them nonetheless. "I was performing a specialized function and collecting a fee for it," he says of his work restructuring bankrupt companies. "But elsewhere on Wall Street, people were substituting balance sheet strength for brains" whenever the new product pipeline slowed.

Even before Mayday struck, the world had begun to change for Wall Street's investment banks and brokerages. The old-style partnership structure limited the amount of capital available and was increasingly proving inadequate for the new environment that was emerging. The capital belonged to the partners: they brought it with them and invested it when they joined the firm, and they contributed to it as the deals they did generated profits that caused the firms' profits to swell. And when partners retired, they could take it with them. Even the biggest partnerships chafed at the limits that this structure imposed on their ability to compete for big underwriting deals.

There were tremendous upsides to the partnership structure as well, especially when it came to managing risk. The partners all had a say in how to deploy the investment bank's assets—what deals to underwrite, what back office investments to make, whom to invite to join the partnership. The thinking was that no partner in his right mind (and they were all men) would take outsized risks that might jeopardize the health of the financial system, because in doing so he would destroy not only his professional reputation and his firm but also his financial security and that of his family. "When a partner put his capital on the line, he knew it was his right and responsibility to ask questions," says investment banking veteran John Costas, a former head of UBS's investment banking operations who launched his own boutique, PrinceRidge, in 2009. "If I'm involved in mortgage-backed securities, and someone else wants to do a big oil trade that I'm not comfortable with or don't understand, I'm going to raise my hand and say so, and tell them they need to explain it to me, because it's my money that's at stake."

Peter Solomon, chairman of his own boutique investment bank, Peter J. Solomon Co., recalled the scene at his former firm, Lehman Brothers, for the benefit of FCIC commissioners during the latter's first round of hearings in January 2010. "The important partners of Lehman Brothers sat in one large room on the third floor of … the

firm's headquarters," reminisced Solomon, who later became vice chairman of Lehman as well as co-head of its investment bank and head of its merchant banking operations. "The partners congregated there [but] not because they were eager to socialize. An open room enabled the partners to overhear, interact, and monitor the activities and particularly the commitments of their partners." There was a reason for any eavesdropping and snooping that took place, Solomon pointed out. "Each partner could commit the entire assets of the partnership" to a transaction.

The cons began to outweigh the pros of this system during the 1960s. That is when the capital constraints of the traditional partnership structure collided headlong with a surge in investor interest in stocks and a corresponding explosion in the trading volume on the New York Stock Exchange, which doubled between 1960 and 1965 and then more than doubled again by 1968. Drowning in the paperwork associated with each trade, Wall Street firms couldn't keep up. For a while, the stock exchange had to shut down every Wednesday, just to give its member firms a chance to balance their books. Even that didn't help; scores of brokerage houses simply collapsed, running afoul of net capital rules when they couldn't prove they had enough capital to support the trading positions that they had taken on behalf of clients. Technology was part of the answer, and so was hiring additional staff to deal with the flood of paperwork—but both would require large, long-term infusions of capital. And as Don Regan, then CEO of Merrill Lynch & Co., pointed out, with the partnership structure "you were never really sure what your capital was going to be."[7]

Dan Lufkin and his two partners, who had cofounded Donaldson, Lufkin & Jenrette (DLJ) in 1959, were determined that their fledgling firm wasn't going to be among the casualties. Although the NYSE's rules at the time required that its member firms be private partnerships, Lufkin believed that survival required major change. So in early 1970 he showed up at a meeting of the New York Stock Exchange Board of Governors, to which he had just been elected, and calmly informed his peers that his firm would file to go public the next day, in order to raise a permanent capital base and put the

business on a firmer footing. The reaction, Lufkin later recalled, "was pretty nasty, old men screaming."[8]

Chief among the opponents was Felix Rohatyn, one of Wall Street's most revered deal makers and managing partner of Lazard Frères, who snarled at Lufkin, "You are Judas."[9] Despite furious opposition from Rohatyn and others (Lazard itself wouldn't go public until 2005, after Rohatyn had left the firm to become U.S. ambassador to France), Lufkin and his partners prevailed, completing their IPO in April 1970, at a price of $15 a share. Although they raised less than they had hoped in the IPO, and although the stock's price languished well below that level during the bear market of the early and mid-1970s, the firm and its partners had pointed the way to an entirely new business model—the publicly traded investment bank, whose executives deployed investors' capital (aka other people's money) in search of the highest possible return.

The pressures on other banks to follow suit increased over the coming years. During the 1970s, new computer technology made markets faster-moving and more efficient, which in turn caused the spread between the bid and ask prices on any given stock (the difference between the price at which investors were willing to buy or to sell) to contract. Mayday knocked one prop out from underneath the old model of investment banking profitability; the computer would do the same to another, since those spreads represented another big chunk of Wall Street's earnings. To stay profitable, investment banks would have to become more active traders, making up in the number of trades what they could no longer capture in profit margin per trade. But that would require capital investment, and one by one, the other Wall Street powerhouses followed DLJ's lead and filed to go public in the 1970s. Some moved rapidly—Merrill Lynch in 1971—and others dragged their heels, worried by how the transformation might affect their culture. The results of this shift from partnerships to public ownership—and the wave of mergers that would follow—would prove dramatic. In 1955, the ten largest investment banks had about $821 million in equity (and subordinated debt) on their balance

sheets; by 2000, that had ballooned to about $194 billion.[10]

Goldman Sachs was the last of the major Wall Street players to make the transition, finally going public in 1999. There, too, partners-turned-shareholders saw the firm's culture shift, slowly but inexorably. Once, partners had been able to describe themselves—with a straight face—as being "long-term greedy." Now, things were different. "There was an awareness that we had a new constituency, and that all of our traditional ways about thinking about the business didn't necessarily tie in to what those guys wanted from us—which was profits and returns," says one former Goldman partner. "At some point along the way, we forgot to ask the question that had always been at the top of the list: is this piece of business worth having?"

Donaldson, Lufkin & Jenrette's open challenge to the Wall Street status quo was just the tip of the iceberg. There were other factors at work that would reshape the way Wall Street worked, notably the bear market of the early 1970s. Why do business at all? Wall Street's largest clients asked themselves. Why not just sit on the sidelines and wait it out until the extreme market volatility became a more manageable environment? Individual investors, who had flocked to Wall Street, savings in hand, during the 1960s, promptly pulled back. Wall Street's fee income from its traditional businesses—buying and selling stock on behalf of its clients and underwriting their debt and equity businesses—was threatened once more.

The solution? New products that would address new concerns, such as how to hedge against market slumps or volatility. Options were one possibility; these gave their purchasers a way to bet on the future price of an underlying stock (and, later, on the movement in indexes and other assets) for a fraction of the cost of buying the stock and with less risk than selling it short. (A short sale, in which investors borrow the stock from a broker and sell it in the hope of repurchasing it at a lower price to return to the lender and pocketing the price difference as their profit, has potentially unlimited risk. If a stock sold short at $10 soars to $100 a share instead of falling to $5, an investor is out $90 a share rather than making a $5-a-share profit.)

Until 1973, options had been used mostly by speculators, but that year a new mathematical model offered a seemingly perfect solution to the problem of how to understand the volatility and risk of a stock and therefore determine the correct price of an option. Devised by MIT professors Fischer Black and Myron Scholes (and immortalized as the Black-Scholes model), the formula gave dealers in the new and rapidly proliferating options products on the fledgling Chicago Board Options Exchange a relatively straightforward way to make a profitable market in options and helped investors use the products with greater comfort. (The model's limitations would become apparent only with the passage of time and in periods of market stress, as I'll show when it comes time to discuss risk management.) Black-Scholes opened the door for Wall Street to begin selling options-based strategies to their clients: investors could, for instance, own a stock but use options to hedge the risk that its price would slump in a bear market. Best of all, in addition to proving that they were paying attention to their clients' needs and wants in a time of stress, brokers could actually earn higher fees from options transactions than they could by executing more plain-vanilla stock and bond trades. It was a win-win situation—at least for the time being.

Globalization also created new market opportunities. In 1971, the United States abandoned the Bretton Woods system of fixed exchange rates, creating a thriving market for options and futures contracts on foreign currencies, such as the British pound, Japanese yen, and Swiss franc. The Eurobond market was another attractive new opportunity. Born in London's financial markets in the 1960s, it involved issuing dollar-denominated debt outside the United States, meaning that the issues didn't need to be registered with the SEC and that the companies selling debt didn't need to abide by U.S. accounting rules.

The Eurobond market was one of the fastest-growing capital markets around—and, like options, it was a lucrative alternative to plain-vanilla bond deals, rewarding underwriters with higher fees. But trying to build a Eurobond business drove home, yet again, the need for a large and stable base of capital. Not only did trying to

grab market share in Eurobonds mean establishing a presence in London, but players such as Morgan Stanley and Goldman Sachs (among the early arrivals) would need to compete with giant commercial banks such as Deutsche Bank and Credit Suisse, institutions that, unlike their U.S. counterparts, faced no domestic rules against using their giant commercial banking balance sheets to help them muscle in and grab investment banking business. (The 1933 Glass-Steagall Act, passed in the wake of the 1929 crash and mandating the separation of commercial and investment banking, was based on the belief that this kind of risk taking on the part of commercial banks had led to the collapse of the U.S. banking system during the 1930s.)

Long before the 1987 crash, all the ingredients required for Wall Street to become a higher-risk environment were solidly in place. "When we went from private partnerships that were the bread and butter of Wall Street's success for many years to publicly traded entities, we may have gained financial capital, but we lost one of those important checks and balances" that stops participants in the financial system from piling on risk, says John Costas. Moreover, publicly traded investment banks found that their new shareholders had a slightly different view of what the institutions' priorities should be than the former partners had had. Both wanted to maximize market share, but one of the trade-offs for access to capital was the demand by new shareholders that the firms also maximize profitability. If Goldman Sachs could earn an ROE of 20 percent or more, why couldn't Merrill Lynch, Citigroup, or Morgan Stanley? That's the kind of question that Wall Street's chief financial officers found themselves being asked year after year, with increasing heat, indignation, and exasperation. Soon they began to share that perspective. "Look, if we're going to be honest with ourselves, we need to admit that we wanted it all," says Lou Gelman, the former Morgan Stanley banker. "We wanted to keep making fat fees, posting high profit margins on relatively straightforward kinds of business. And after 1975, the writing was on the wall: that was never going to happen again." Wall Street, as it had functioned for decades, had undergone an irrevocable change.

one that made its core utility function take a backseat to its ability to devise new and exotic products.

From Cornflakes to Raisin Bran

In Marty Fridson's view of the world, today's Wall Street has drifted far afield from its roots as a utility, driven there by the winds of change blowing through the financial system and originating outside it. He sees clearly through the rhetoric that the investment banks still put forward when describing their role, to the heart of the matter: Wall Street's real focus is profits, not its utility function. And after a quarter of a century spent warning investors when one of Wall Street's cherished junk bond deals is nothing more than a pig dolled up in lipstick, Fridson is willing to speak his mind. It is no longer about the process, he insists; it's about the products. "I tell anyone I meet who's starting out in banking or research today, Wall Street is really in the breakfast cereal business," Fridson says bluntly. "Forget the idea of having a big mission. They're selling stuff to people, and after a while, that stuff becomes a commodity, like cornflakes. And then it's time to come up with a new, better idea, something that will become the financial equivalent of peanut-butter-flavored Cap'n Crunch."

How did fees earned from selling "stuff"—whether it's junk bonds, CDOs, or exotic derivatives—come to replace the fees captured as a result of the process of bringing together investors with those in need of capital? It all dates back to the changes that began in the 1970s. Wall Street's investment banks had always battled ferociously for the top spot in the league tables, the monthly, quarterly, and annual rankings that show which firms dominated the underwriting of what kinds of securities for what kinds of companies. The turmoil caused by Mayday introduced a new, cutthroat element of price competition to that already feverish competition. Most institutions that survived the 1960s and 1970s, whether through some kind of strategic planning or through trial and error, ended up devising several different ways to try to boost

their bottom line in a world of perpetual downward pressure on profit margins. A failure to replace trading revenues lost to technological innovation and deregulation could mean the institution's collapse, they were all well aware.

Sallie Krawcheck, who studied the investment banking business first as a research analyst and head of research at Sanford C. Bernstein and later as chief financial officer at Citigroup, notes that every year for thirty years after Mayday, the revenue that Wall Street collected in the form of trading fees declined. Every year, investment banks needed to generate more—not less—income and profit. The only solution? "You had to start running faster and innovating," says Krawcheck. "The best way to increase profits in that environment was, firstly, through innovation or by increasing the amount of leverage on your balance sheet."

The need for product innovation was made more pressing by the breakdown in long-term client relationships. The House of Morgan had ties to AT&T that dated back to a 1906 bond underwriting; Morgan Stanley inherited the investment-banking portion of those ties after the passage of the Glass-Steagall Act forced the venerable banking institution to separate its commercial bank from its investment banking operations. Between 1936 and 1968, AT&T steered $4.68 billion of underwriting business to Morgan Stanley, yielding lucrative fees.[11] And AT&T was just one of the forty-one major corporate clients that used Morgan Stanley as their sole lead manager on deals like this; 80 percent of their top clients would deal with no one but Morgan Stanley. So when one loyal client, IBM, turned to Salomon Brothers to handle its 1979 bond deal, the writing was on the wall: client loyalty was becoming a matter of the question "What have you done for me lately?"

Sure enough, clients began shopping around for the best deals. That, in turn, put more pressure on investment banks to go public, since part of offering a client the best deal increasingly required the investment bank to put its own capital on the line first, by doing "bought deals" (buying the securities for resale to investors), and later, by providing bridge financing. But clients weren't only shopping for the best deals; they also wanted the brightest ideas. To

return to Fridson's breakfast cereal analogy, Main Street was no longer content with being served cornflakes every day of the week. If a company needed capital, it wanted the right kind of capital, and if the increasingly sophisticated capital markets meant that was a highly structured customized transaction, well, so much the better for both the company and the investment bank, which could pocket a larger fee on the deal.

The cornflakes era had survived as long as it did not just because it worked (it had helped the government finance wars from the Revolutionary War right through to Vietnam, assisted states in building canals for transportation, and created extraordinary wealth for the railroad barons and others) but because Wall Street's clients didn't realize that there were—or could be—alternatives to cornflakes that would meet their needs or cater to their tastes more precisely. To stretch the analogy further, as long as consumers can rely on cornflakes to be readily available at a reasonable price and to get them fueled up for the day, they may not actively hunger for alternatives. But as soon as a smart researcher discovers that a significant minority of those cornflakes consumers love eating raisins atop their cereal, and realizes that that group might pay much more for a specialized product that satisfies their craving for raisins, bingo—Kellogg's Raisin Bran is born, and the world changes. Consumers flock to the exciting new product; to keep their market share, cornflakes producers slash prices and profit margins.

On Wall Street, Salomon Brothers was one of the firms playing the role of the manufacturer of Kellogg's Raisin Bran. As a firm that had specialized in bond trading, it watched its profit margins shrink and plotted ways to escape its allotted role in the Wall Street scheme of things. Through a combination of price cutting and innovation, Salomon parlayed its bond market trading prowess into more underwriting mandates from firms such as IBM, chipping away at the market share of their white-shoe rivals in a process that Pete Peterson, a financier and onetime secretary of commerce who became chairman and CEO of Lehman Brothers in 1973, referred to as "de-clienting."[12] The firm, whose dominance of the bond market was matched only by its ambition to capture an ever larger share of

Wall Street fees, became an expert innovator. Developing successful new products—even entirely new markets—would, Salomon's leaders calculated, be one surefire way to escape the "muddle in the middle" in investment banking and catapult a second- or third-tier financial institution to the top of the heap, alongside the likes of Goldman Sachs.

One of Salomon's chief bond gurus, Lewis Ranieri, originally had dreamed of becoming a chef in an Italian restaurant. When his asthma made it impossible for him to survive long days in smoky, steamy kitchens, he went to work in the mailroom at Salomon Brothers. It was the first step on his way to being anointed by BusinessWeek in 2004 as one of the greatest innovators of the last seventy-five years—and, later, to being referred to as one of the chief architects of the 2008 market meltdown. Unable to craft mouthwatering confections in a kitchen, Ranieri set about designing equally appetizing products for investors' portfolios: mortgage-backed securities.

The idea of taking homeowner mortgages, bundling them together, and selling them had been introduced in 1970, with the launch of the first Ginnie Mae (formally known as the Government National Mortgage Association) securities. The concept was very simple: the financial institution (or issuer) trying to sell the securities rounds up enough mortgages, pools them in a special-purpose vehicle (such as a trust), and then underwrites bonds issued by that special-purpose entity. To all intents and purposes, it was like any other underwriting, except that the issuer wasn't a real company, and the investors were getting a stake in a portfolio of some bondlike securities rather than a corporation. The cash from the sale goes right through the trust and back to the originator(s) of the mortgages, typically a bank or savings and loan institution. The way the bonds were priced and traded would depend on the kind of assets they contained—what kind of mortgages (commercial or residential) and the credit quality of all the home buyers taken in aggregate.

"No new product succeeds unless it's in the interest of investors," argues Michael Lipper, president of Lipper Advisory Services. In the

more than thirty-five years since Lipper first created a series of indexes to track the performance of mutual funds, he has watched the Wall Street innovation juggernaut produce a seemingly endless series of new products, or new twists on older products, all in hopes of gaining at least a momentary edge in the constant battle for market share and fee income. "Chuck Prince's comment about keeping dancing as long as the music was playing got him a lot of hostile feedback, but what people often overlook is that it takes two parties willing to dance together," says Lipper, referring to the former Citigroup CEO's comment. Any product that succeeds, such as mortgage-backed securities, Lipper believes, does so because it meets a need for both the issuer (the banks and savings and loan institutions) as well as the investor. "Wall Street doesn't go around trying to invent things just for fun, and they couldn't sell them if the product didn't meet some kind of need on the part of the investor. Wall Street institutions don't go around holding guns to the heads of investors or their other clients, and insisting that they buy this structured note or the other derivative contract."

Indeed, it's pretty much impossible for Wall Street to do anything like that in the earliest stages of a new product's development. When Ranieri began to turn the fringe business of mortgage securitization into a money spinner for Salomon and for Wall Street as a whole in 1977 (at its zenith, Ranieri's mortgage finance group would generate half of Salomon's profits), mortgage-backed securities were legal investments in only fifteen states; even where legal, they weren't necessarily respectable. But it became clear, as Ranieri fought a two-front war to win investor understanding and legal recognition of asset-backed bonds, that the new products filled needs on both sides. The 1970s were the era of market volatility, but also the decade in which the first baby boomers began purchasing homes. Banks were overwhelmed; every loan they made was a fresh inroad into their capital base, and demand was such that they couldn't cope. But if they could originate the mortgage loan and then sell it to another nonbank investor—well, that instantly removed any artificial constraints to issuing a mortgage. A home buyer in Boise, Idaho, wouldn't be turned down for a loan

simply because that city's financial institutions—the only lenders directly available to him or her—had already made too many home loans.

The advent of the mortgage-backed securities market meant that home buyers indirectly had access to the entire money grid known as Wall Street. The banks were happy—they could keep collecting their fees for originating mortgages and maintain their other relationships with their clients. Home buyers were happy—they got their mortgages, often at a lower cost. (Ranieri figured that the evolution of the mortgage-backed securities market helped shave two percentage points off the cost of a typical mortgage simply by creating a more efficient market.) Investors eager for bondlike investments with higher returns than Treasury securities began snapping up the securities once they became more familiar with the structure itself. And the issuers—the Wall Street institutions such as Salomon Brothers—were happiest of all. With an investment of time, money, and brainpower, they had created a viable new product, one that would become central to the financial system, earning them lots of fees. And while it wasn't as venerable a business as underwriting or trading on behalf of corporate clients, it was just another way of fulfilling the same core function of Wall Street, bringing together those who needed capital with those who had it—in this case, home buyers and their banks with outside investors such as pension funds and mutual funds. It was just doing so with an emphasis on a proprietary product that happened to generate heftier fees than the traditional process had done.

Innovate or Die

At a lavish dinner celebrating the fortieth anniversary of Institutional Investor magazine in 2007, Henry Kravis, a cofounder of the giant buyout firm KKR, was one of the evening's honorees—the forty "Legends of Wall Street." (That group also included John Gutfreund of Salomon Brothers.) In his speech, Kravis chose to laud Michael Milken, the investment banker who had popularized the

"junk bond" during the 1980s. Without Milken, Kravis told the audience, KKR couldn't have done the gargantuan deals that made it famous, and the entire buyout business (which had generated $357 billion in deals in the United States alone the previous year, each of which produced massive fees for Wall Street investment banks) would have been stillborn. Kravis called for Milken to stand up and be acknowledged. With the Wall Street audience applauding and even whooping and cheering, Milken, sitting at a table in the midst of the crowd, rose to acknowledge the acclaim.

By the 1980s, innovation became the way for every investment bank aspiring to be ranked alongside Goldman Sachs and Morgan Stanley to achieve that dream. The smaller the firm, the more ambitious and aggressive it had to be in order to grab market share; the more willing to bet the house on a completely new idea. That is what Ranieri had shown with securitization at Salomon Brothers and Michael Milken would demonstrate at the firm that became known as Drexel Burnham Lambert. The venerable Philadelphia-based firm was still Drexel Firestone when Milken arrived there as a bond salesman in 1970. It had been in partnership with the House of Morgan until the passage of the Glass-Steagall Act in 1933, but like many of its peers had since undergone a long, slow slide. Three years after Milken joined Drexel, I. W. "Tubby" Burnham, head of a smaller but profitable investment bank, purchased the firm; when he learned that Milken, one of the smartest of Drexel's traders, was on the point of leaving because his bosses wouldn't give him any capital to use to trade, Burnham promptly handed over $2 million. In a single year Milken doubled it, and Burnham raised the capital available to him to $4 million.[13] The two men then struck what would become one of Wall Street's most infamous compensation agreements: Milken would collect 35 percent of his group's revenues, after the costs of running the business were deducted. "It was a good deal for us, and a good deal for him," recalled Fred Joseph, who later became Milken's boss. "Yes, it led to one year where he ended up doing so much business that he made $550 million personally, but he made even more for the company."

Milken's coup wasn't the invention of junk bonds; in one form or another they had been around since at least 1909, when Moody's began rating bonds issued by railroad companies and found that the credit quality of some wasn't high enough for them to be described as "investment grade," in the Wall Street jargon of today.[14] Milken transformed the market, realizing that to sell these lower-quality bonds, an investment banker needed to woo investors with the company's story, in the same way that a stock salesman would pitch the potential for future growth of a business. On the surface, the bonds were indeed junk—their credit ratings signaled that the company carried a heavy debt load or its business was troubled. But Milken could see that on a risk-adjusted basis, the prices for these bonds were too low, partly because there wasn't an active secondary market (there's no equivalent of the stock market for bonds) and partly because investors weren't evaluating them the right way.

Milken persuaded investors to look past the ugly credit rating to the underlying potential of the business. It was only natural, he argued, for some companies to have a lower credit rating, but the risk that they'd default on that debt, given the underlying business story, was far lower than the market price of the debt suggested. Milken succeeded so brilliantly that by the late 1970s, a host of companies that previously had been shut out from selling bonds because of their less-than-pristine credit rating were now able to issue debt—through Drexel Burnham, of course—to a growing coterie of investors that Milken had cultivated. "The first year that new issuance hit $1 billion was 1977," recalls Marty Fridson, who in a few years' time would decide to specialize in analyzing junk bonds. When Fridson made that move, his colleagues thought he was a bit nuts; the products were new and the move was risky. "But it was a great career maker, because too few people were really studying these products, and the lack of understanding" created opportunities that Fridson believed trumped the risks.

Junk bonds, like mortgage-backed securities, were, in their earliest and simplest form, great for both investors and issuers. Investors able to do their credit homework got access to a whole

new pool of higher-yielding bonds, while the availability of the capital in this new market helped jump-start a host of new businesses in the gaming, telecommunications, and media businesses. Multibillionaire Steve Wynn relied on junk bonds to build his casino empire, as did Ted Turner in expanding his broadcasting business (including CNN). As these and other moguls caught on to this new type of financing, the early days of the junk bond revolution were good for everyone. The sheer newness of the junk bond market and the fact that no one but Milken and his team of specialists seemed to understand it meant that Drexel could charge an astonishing 4 percent of the proceeds of a junk bond issue in fees, compared to 1 percent for an investment-grade corporate bond issue. And there were more junk issues coming every year, as a new breed of financiers such as Henry Kravis used junk bonds to finance their buyouts.

That meant hefty profits. In 1977, Drexel reported about $150 million in revenue; by 1985, that had soared to about $2.5 billion, and the book value of its stock (which didn't trade publicly) had increased more than tenfold. By 1986, when its revenue hit $4 billion, Drexel's estimated net earnings were $545.5 million, making it the single most profitable investment bank in the country. None of its rivals could sell a billion-dollar deal in hours, as Milken boasted he could; the network of investors he had carefully cultivated was the ace in the hole that allowed his group (known as "the Department") to dominate Drexel, and Drexel to dominate Wall Street. Meanwhile, Salomon, the other upstart firm, had parlayed its dominance in other parts of the market (including the burgeoning world of securitization) into the position of Wall Street's second-most-profitable firm, earning about $516 million (although it took twice as much capital to generate that kind of profit, making for a much lower return on capital).[15]

But every successful innovation carries within it the seeds of its own potential destruction, and Drexel's junk bond empire would be no exception. First, the product itself became less cutting-edge with every year that passed, and, as competitors became more adept (or hired some of Drexel's pros), the firm slowly but steadily lost

market share. Profit margins also shrank; in the case of junk bonds, the average fee an investment bank could demand for underwriting a junk bond issue fell steadily, to 2.1 percent by 2003 and a low of 1.5 percent in 2006. As with any hot new product, from the pocket calculator to the DVD player, on Wall Street the passage of time and greater sophistication makes it easier for rival manufacturers to offer the same product profitably at a lower cost. "The increasing complexity of products is a direct result of the fact that you can't get a patent or copyright for your innovations on Wall Street," explains Sallie Krawcheck. "So if you make something so complicated it will take your competitors a long time to figure out and replicate, well, that's great. The longer it takes, the longer your advantage lasts."

The awareness that fees are falling (or about to fall) puts the pressure on an investment bank to compensate for lost revenue. If the margins are shrinking, then, as Krawcheck points out, it's up to the investment bank to somehow replace that revenue, whether by boosting volumes or adding complexity. In the case of products such as junk bonds (or CDOs), the logical first option is to ramp up the number of transactions. And that's exactly what happened at Drexel. Fred Joseph, named president of the firm in 1984 and CEO in 1985, had promised Tubby Burnham that within the next decade he would use Drexel's junk bond prowess to transform it into a firm that was even more powerful than Goldman Sachs, already considered the gold standard on Wall Street. "If we'd been asked publicly if we wanted to be Goldman Sachs, we'd probably have denied it, but secretly a lot of people coveted what they saw as Goldman's cachet," said Joseph, comparing this "Goldman envy" to the same feeling that hits a bright kid with a blue-collar background who makes it to Harvard or Yale only to find himself among privileged prep school grads who take their advantages for granted. "It wasn't that we had a chip on our shoulder; just that many people figured they were just as bright as anyone at Goldman, but even then they and Morgan Stanley were the firms that got the automatic respect of every potential client. All they had to do was show up, some people would complain, to knock us out of the running for a deal." That's what Drexel's junk bond prowess helped

change.

But Joseph couldn't reshape Drexel's culture, which was now dominated by Milken's group. And that group, it seemed, was playing fast and loose with the rules to drum up deals and profits. No one could figure out all that they were doing or get them to toe the line. Milken and others created a number of limited partnerships of dubious legality that allowed them to make even more money than Drexel itself and of which even Drexel's top executives and board members weren't aware. Ultimately, Milken refused to cooperate with Drexel's own internal investigation into the possible involvement of the department with insider traders Ivan Boesky and Dennis Levine. To settle the case, the firm forked over what was then the largest securities industry fine in history—$650 million. Milken, indicted on a variety of securities offenses, ended up serving nearly two years of a ten-year sentence after pleading guilty to six felonies. By the time that Milken emerged from jail in early 1993, Drexel had been gone for years. Joseph himself was barred from actively running the new investment boutique he co-founded; until the day of his death in November 2009, he remained restricted to the role of co-head of corporate finance.

The roots of the problem, of course, were Milken's excesses and the risk management and governance failures those revealed. "Frankly, while I feel bad for people who worked at Drexel and had nothing to do with the high-yield bonds and lost their jobs and life savings, I don't feel bad that the firm collapsed," says Fridson today. "Any other firm could have done the same thing that Drexel did by committing almost all its capital to that one ultrasuccessful product line, but they didn't—and they were right, because that's too risky." And that's another reason it is perilous for any investment bank to rely on any single new product as a steady source of profits. In the case of junk bonds, by the time that Milken ran afoul of regulators, the junk bond cycle was coming to an end—a prospect to which he and others at Drexel seem to have blinded themselves. "Well, we only realized it in theory," Joseph admitted only a few months before his death. Interest rates jumped, the

economy slumped, and suddenly companies that had issued junk bonds began to default, at a rate of one in ten. The buyout kings, including Kravis, put their deal making on hiatus, cutting off the flow of fees to Drexel. Even if Drexel hadn't run afoul of the securities laws, its heavy dependence on a single product that was about to hit a cyclical slump, coupled with the fact that it was using its own capital to buy back some of those distressed bonds from unhappy investors, likely would have wreaked havoc on its profits and balance sheet. In 1990, Drexel filed for bankruptcy.

As Drexel's experience with junk bonds illustrates all too clearly, success requires more than one brilliant idea. To succeed at the innovation game, an investment bank needs a string of them, carefully developed so that as one is flagging or hitting a cyclical low, the next is appearing on the horizon. But how many "new new things" are there on Wall Street, really? In practice, Wall Street ended up turning to other, more dangerous ways to artificially prolong the profitable life span of its innovations, such as leverage and doing lower-quality deals. As Mike Mayo told the FCIC, the world of banking and investment banking became "an industry on steroids," whose loan volumes grew at about twice the rate of the underlying economy. "[Banks] pushed for loans that should never have been made," Mayo said. Ranieri's brainchild fell victim to this, as investment banks took the mortgage-backed securities he had pioneered and turned them first into CDOs, then into subprime CDOs, then into more complex CDO-squared or CDO-cubed structures. Ranieri began warning investors publicly about the problems with these later, high-risk incarnations of his creation around 2006. (In a 2008 interview, he would describe the increasingly exotic features of CDOs, conceived as a way to keep the fees flowing and the profits climbing, as "loans [that] need the tooth fairy to keep up their values.")[16] The more successful a new product or strategy is, the harder it becomes for an investment bank to stay disciplined, and Salomon (which would be caught up in a Treasury-bond trading scandal in 1991) and Drexel were no exception to that rule. Salomon would survive, although not as an independent firm (it became part of what is today Citigroup);

Drexel's deal makers moved on to try to work their magic at other investment banks and its alumni can still be found scattered across the Street.

Chasing Goldman Sachs

One of the reasons most of Wall Street's investment banks have spent the last two decades chasing Goldman Sachs—or at least lusting after and trying to replicate its profitability—is the fact that Goldman is one of the few firms that has managed repeatedly to get the innovation process right. Part of the reason, rivals say now, is that the firm didn't place all its bets on a single product or even a single strategy. "They were about the only firm on the Street that saw the kinds of changes that were coming and planned for them strategically," says one former senior figure from another investment bank. "Of all the firms on the Street, Goldman Sachs is the one that behaves most strategically, nearly all of the time. When it doesn't know what kind of new business model will emerge, it puts a bet on everything, in order to be sure it will be part of whatever emerges the winner." That's what happened in the late 1990s, when the SEC ordered some of the most sweeping changes to the way stock trading took place on Wall Street. The New York Stock Exchange lost its control of trading in the stocks listed on its own exchange to rival start-up electronic networks. Goldman had taken a stake in a number of these; ultimately it used its clout to arrange a merger between one of the winners, Archipelago, and the venerable stock exchange. Today the combined entity is run by a former Goldman Sachs managing director. "That's just what they do," says the former rival with a shrug. "Their approach to innovation is opportunistic."

That approach dates back to the 1980s, when two of Goldman's former leaders, Robert Rubin (who would go on to become Treasury secretary for the Clinton administration before returning to work on Wall Street, this time at Citigroup) and Stephen Friedman, realized that they had two options if their white-shoe investment

bank was to retain its elite status. Midsized firms were doomed, they concluded; either they would collapse or become acquisition targets. That left Goldman with the choice of either being a great boutique investment bank or making the leap and becoming a giant global financial institution. Rubin and Friedman decided on the second course of action.[17] (In the 1990s, faced with the same dilemma and reaching exactly the same conclusions that being stuck in the middle was a recipe for disaster, Bill Hambrecht's successor at the head of Hambrecht & Quist, Dan Case, decided that even survival as a boutique was doubtful in a world now dominated by giants; he decided to sell the firm to what was then Chase Manhattan Bank, a predecessor of today's JPMorgan Chase.)

Goldman recruited quantitative analysts—known as quants—such as Fischer Black to help them come up with new products and fresh approaches to trading, and tried to identify new business opportunities wherever they could. The firm needed to devise new products and business lines—and it needed to be the first to launch them, Friedman believed. "If we're not leaders in innovation, we won't be fast enough to reap the really good profits that the innovators get—and deserve."[18] The 1970s bear market had left many companies with depressed stock prices and discontented shareholders, making them vulnerable to hostile takeovers by a growing array of corporate raiders who were beginning to make their names on Wall Street. Goldman's bankers began offering what they labeled "tender-defense" services to actual and potential targets. The first few times their bankers called on a target company, their offer of help was politely declined. They persisted, and beleaguered executives quickly realized how useful it could be to have Goldman's financial markets know-how on their side in a battle for control of their companies. Ultimately Goldman managed to parlay this into a business that generated a steady stream of income each year. CEOs, reassured by the fact that Goldman refused to work for any of the raiders, were apparently quite happy to fork over annual retainers to the investment bank in exchange for the right to summon its team of defense specialists should a raider come calling. (In contrast, many of Goldman's rivals seemed more

like mercenaries, working on an ad hoc basis for either raiders or targeted companies, depending on who was willing to pay a fatter fee.)

In addition to creating its tender-defense business and its push into overseas markets, Goldman Sachs acquired J. Aron, a veteran commodity and futures trading business. As Rubin and Friedman had recognized earlier, and as Dan Case would later, Herb Coyne of J. Aron saw Wall Street was changing; his firm wasn't likely to survive if it remained a stand-alone business. Coyne's willingness to sell gave Goldman a toehold in these high-margin businesses (J. Aron's business lines generated a third of Goldman's profits with only about 5 percent of the staff) and helped the company prepare for a still more significant change, one that the next chapter will explore in greater detail—the transformation of Goldman from a firm that simply executed transactions for its clients to one that used its own base of capital to take risks, investing or trading on its own behalf.

Collectively, those innovations resulted in the creation of a business model that increasingly appeared to the rest of Wall Street like an unbeatable juggernaut. Between 1996 and 2008, Goldman Sachs's return on equity averaged 24.4 percent, dwarfing those of its rivals. Lehman, its nearest rival for most of that period, managed to earn 19.2 percent, while Morgan Stanley came in third, with an ROE averaging 18.6 percent. That was a wide gap, and one the outside investors in the now publicly traded investment banks badly wanted to close. It was now that the IPOs of the investment banks proved to be a double-edged sword. They provided Wall Street investment banks the capital base they needed to expand globally and to innovate as well as giving partners the ability to lock in their profits and reduce their risk. (The Goldman Sachs IPO alone created hundreds of instant paper millionaires out of all its partners.) "It was very, very tempting to sell to the public," says Sam Hayes of the Harvard Business School. "The claim was that they needed the capital, but to this day I think it was just as much about greed. An IPO gave partners in an investment bank the opportunity to sell, or at least value, their ownership of the firm at a multiple of book

value."

The IPOs had made bankers richer and helped them expand their business, but they had also made that business more accountable to outsiders, whose definition of success involved generating the biggest return on equity within the industry and boosting profits quarter after quarter, year after year. Large shareholders, including mutual fund managers, would meet with the CEOs of large publicly traded investment banks and challenge them—not always politely—to do whatever it took to boost the firm's return on equity to match that of Goldman Sachs. How would they get the extra 5 or 10 cents in earnings per share that investors wanted this year? What business could it come from? What product could be created and sold, rapidly and profitably? And what could they do to maintain those profits over the long haul, when the newness wore off and rivals started to imitate them?

The pressure filtered its way down the food chain. "Every quarter, we'd get some kind of note about how this would be the biggest or most important quarter in the firm's history, asking us to keep focused and deliver the results," recalls Peter Blanton, whose career as an investment banker has taken him to Citigroup, Credit Suisse and Lehman Brothers, among other firms, and who now works for a boutique firm. Bankers found it harder to say no to a piece of new business, even if it looked a bit risky or otherwise unappealing. The scramble for market share and a bigger ROE came to look almost like the cold war arms race, with Wall Street firms rolling out one innovation after another—the block trade, zero-coupon convertibles, PIPE (private investments in public companies) deals. Then, as the financial markets struggled to recover from the aftermath of the dot-com collapse of 2000, came the CDO revolution. Not only were these new products part of the largest and most liquid markets out there—the bond market and the real estate market—but financial wizards could make them even more profitable and strip out the risk as well (or so they claimed).

Innovation, says Tom Caldwell, had finally gone too far. Caldwell runs a Toronto-based investment firm and owns stakes in stock exchanges globally; his career as a trader and investor dates back to

the early 1970s, just as Wall Street began its metamorphosis. "I watched this happen, but I didn't get alarmed until banking started becoming exotic," he says. "Banking should be boring." To Caldwell, Wall Street's role remains all about providing capital to growing companies—and withholding it from others, as it has done recently in the case of the automakers or companies such as Kodak, when their leaders showed an inability to manage or to innovate. "The business of Wall Street isn't innovating, or creating some flashy new product to boost its own profits; it's providing the wherewithal for corporate innovation," he argues. Whenever financial innovation—the kind Wall Street indulges in—ends by making capital less available to corporate innovators, that is when Caldwell knows Wall Street has drifted too far from its mission. "That's what happened when the credit markets froze; it was the last sign of that trend."

Indeed, at the height of the exotic product innovation craze in 2005 and 2006, fueled by the need of Wall Street to keep dancing while the music played, few products were being developed to help improve access to capital for companies. "It goes in cycles," says Rob Kapito, president of BlackRock. "When we started out in this business, oh, 150 or so years ago, if we developed a new security, it had to have a purpose and it had to work the way we thought it would. It had to be something that was good enough for your mother to buy. But over time, there's a tendency for things to go crazy, for innovation for innovation's sake to take over." Kapito agrees with Caldwell that Wall Street lost its way. From his years working at an investment bank before moving to the sell side (joining the ranks of those who invest in the products Wall Street creates or underwrites) at BlackRock, he figures he can identify a bond-based security that serves a purpose for the investor, as did the first mortgage-backed securities or junk bonds. The innovative products being pitched to buy-side firms such as BlackRock by 2006 didn't qualify, he says. "If we had created a security like some of those [that are collapsing and causing large losses], we would have been fired, and the firm would have done whatever it took to make reparations to their clients," Kapito insists.

Ultimately, innovation for innovation's sake put Wall Street in peril when investment banks began packaging lower-quality, higher-risk deals into these complex mortgage-based securities, and then using leverage to make the transactions more profitable still. As Lloyd Blankfein told the FCIC inquiry in early 2010, the average annual growth in new mortgage loans was about 6.3 percent between 1985 and 2000, but between 2001 and 2006, it had jumped to 10 percent. And subprime loans were making up a greater and greater portion of all the new lending: from 2 percent in 2002, new subprime loans soared to make up 14 percent of all new mortgages in 2008, Blankfein testified.

But then, to keep the deal machine whirring, Wall Street and its mortgage suppliers—firms such as Angelo Mozilo's Countrywide—simply overlooked the fact that they had lent all that it was prudent to lend to creditworthy buyers and moved further down the quality spectrum. They began lending more than was prudent, offering loans for 100 percent of the purchase price of a home, and reaching out to buyers with limited incomes or poor credit ratings. About 7 percent of all the mortgages repackaged into asset-backed mortgage securities in 2000 were subprime loans, or about $74 billion. By 2004, subprime lending made up 22 percent of the market, or about $608 billion by some estimates. True, Wall Street CEOs such as Chuck Prince, Stan O'Neal, or Richard Fuld weren't personally signing off on subprime loans or undertaking risky, highly leveraged buyouts. But their willingness to embrace that risk and their reluctance to adopt a cautious attitude toward the products on which so much of their revenues and profits now depended ensured that firms such as Countrywide pushed their own sales forces to generate more and riskier home loans.

That kind of reckless competition should have made it clear that a balance sheet blowup was looming, says financier Wilbur Ross. "When Salomon Brothers started out, they made their money trading [Treasury bonds]. Well, there's a risk in trading them, [but] it's a market timing risk, not a credit risk." When Wall Street branched out and began to rely on junk bonds and securitization to generate profits, that meant new risks, Ross adds. Every innovation

brought new risks to Wall Street. “The whole thing was getting bigger and bigger and bigger, but the basis on which people were competing wasn’t innovation anymore, because that didn’t go far enough. But you can be the biggest deal maker in the world if you don’t care, if you go far enough down the food chain.” By the autumn of 2008, Wall Street had only a handful of very large and highly innovative firms, most of which seemed to the best-informed insiders to be teetering on the verge of bankruptcy and could only be saved by an unprecedented government-organized bailout.

Wall Street, at its best, had proved to be a very good innovator, spotting opportunities and turning them into creative products that its clients needed and wanted and that generated lucrative enough fees for firms to not only survive the dog days of the 1970s but grow dramatically during the 1980s and 1990s. But chasing after fees, it was becoming increasingly clear, could be a dangerous pastime. Indeed, the more that Wall Street managed to collect in fees, the more risk lurked in the system. The wizards of Wall Street may have been very adept at devising ever more exotic and profitable twists on all kinds of classic products, but like the sorcerer’s apprentice in Goethe’s poem, they failed to realize the risk and danger associated with that financial alchemy.

Later, Wall Street observers would begin to focus on the role that innovation played in the cataclysm. Paul Volcker, the former Federal Reserve chairman, was among those who spoke out; describing the biggest useful financial machine as the automated teller machine, or ATM, he told a conference of bankers at a luxurious country house hotel in England that he wished “someone would give me one shred of neutral evidence that financial innovation has led to economic growth—one shred of evidence.”[19] Testifying to the FCIC a few weeks later, Mike Mayo was even more blunt. “Wall Street has done an incredible job at pulling the wool over the eyes of government and others,” he declared. Not only did the economy work just as well without CDOs, the risk “was more obvious and easy to see.” Certainly, as financial market innovation ran amok in the early years of the new millennium, the risks only increased, as new Wall Street players displaced those on Main

Street as principal clients of the investment banks, causing the Street to drift further still from its traditional role in the economy.

CHAPTER 3

What's Good for Wall Street Is Good for … Wall Street

How Wall Street Became Its Own Best Client

Over the years that Mark Vaselkiv and Dave Giroux had worked on Wall Street's buy side as portfolio managers at T. Rowe Price, selecting investments for an array of bond mutual funds, they had become accustomed to having Wall Street bankers call or show up on their doorstep to pitch the latest structured product or market a hot new deal. So it was with a sense of something being slightly askew that the two men boarded the high-speed Acela train in Baltimore one morning in the early spring of 2005. Their destination: the New York head office of JPMorgan Chase, where they would meet with Nils, the salesman the bank had assigned to cover their account.

Vaselkiv and Giroux wanted to talk to Nils about the leveraged loans that investment banks such as JPMorgan Chase were issuing at an ever more rapid clip to help private equity funds finance their ever-growing string of buyout transactions. Loans of this type are the least risky investment to own since they rank above bonds or stocks in a company's capital structure; in the event of a bankruptcy, lenders have first claim on assets. But the Federal Reserve's commitment to fighting a recession in the wake of the dot-com bust and the 9/11 terrorist attacks meant that interest rates had remained at rock-bottom levels for so long that the world was awash in money. With every day that passed, it was becoming harder for investors such as Vaselkiv and Giroux to find bonds to

buy that offered a yield high enough to offset the potential risk of the investment. Vaselkiv thought that leveraged loans just might be part of the answer to this conundrum.

The T. Rowe Price managers were hardly minnows in the fixed-income world. Together, the two men managed about $25 billion of investor funds; Vaselkiv figured that that should help them win a share of some of the leveraged loans. Even better, he calculated, was the fact that T. Rowe Price bought bonds and other products and held on to them for longer-term returns; the firm's investment managers didn't try to capture profits by trading them rapidly, as hedge funds tended to do. Historically, being an owner rather than a trader has been a desirable trait in the eyes of Wall Street when it has been trying to match up companies in need of capital with the right kind of investor. Still, Vaselkiv couldn't quite shake a sense that all was not quite right with the picture. What was he doing, boarding a train to visit a salesman to ask for access to a product that in prior years the same salesman would have been pleading with him to purchase?

It was odd, especially since Vaselkiv calculated that JPMorgan Chase probably could use some new buyers for these loans. The recent buyout boom had left companies carrying outsized amounts of debt on their balance sheets, and the economic environment was starting to wobble amid sky-high energy prices and rising interest rates. "The buyouts were getting larger, the loans were getting bigger, and we all anticipated that at some point defaults would rise," Vaselkiv says. "No question, the cycle would come to an end." That was just why he was interested in owning the loans, rather than the more readily available junk bonds: in that kind of scenario they would hold their value better. "By the same token, we figured that the investment bank would be interested in us as a new client."

On their arrival in New York, Vaselkiv and Giroux traveled across town from Pennsylvania Station to JPMorgan Chase's Park Avenue offices. They sat with Nils, their salesman, and made their pitch: T. Rowe Price, one of the largest mutual fund investment groups in the country, was eager to become an investor in leveraged loans. It should have been the answer to a Wall Street salesman's prayer.

Vaselkiv, however, was left dumbstruck by the response. "I'll never forget this, to my dying day; he looked at me and said, 'We don't need you,' " Vaselkiv recalls. This was no pleading Wall Street salesman: The shoe was now on the other foot. Vaselkiv realized now what had been bugging him about the idea of the trip to New York in the first place: He and his firm, which managed hundreds of billions of dollars of assets, had had to bang on the bank's door and ask humbly to be considered as a worthy buyer. Not only had he done so, but he and T. Rowe Price had been rejected out of hand.

Wall Street had changed: Giant investment firms such as Fidelity and T. Rowe Price were now less important to an investment bank than were smaller but more profitable hedge funds, which generated more trading fees and made buy decisions faster than the old-style mutual funds. Nils explained to Vaselkiv that JPMorgan Chase had about twenty-seven collateralized loan obligation (CLO) products in various stages of development. "Each and every one of those [leveraged] loans would go into those products, which in turn would be resold," Vaselkiv recalls. "He said there wasn't going to be any product for people who asked as many questions about a deal as we did." T. Rowe Price, the seventy-year-old $400 billion behemoth, had just been royally dissed by a mere salesman.

But Nils was right. JPMorgan Chase didn't need the traditional buy-side clients nearly as much as it had a few years earlier; neither did the other Wall Street institutions. Nor did these investment banks rely nearly as much on their classic corporate finance clients, companies such as Coca-Cola or Verizon that were on the other side of the money grid from investors like T. Rowe Price. These Main Street clients still called on Wall Street firms to help them raise capital or advise on merger transactions, but their significance paled when compared to that of the giant buyout funds. In the 1980s, making the plain-vanilla loans to those big Main Street clients had still generated the vast majority of JPMorgan's profits; but by the mid-1990s, that picture had changed irrevocably with fees from trading and investment banking—and increasingly, from derivatives—generating $3 out of every $4 in profits. In 1997, only about 2.3 percent of the IPOs Wall Street firms underwrote were done on

behalf of a buyout firm. A decade later, in 2007, nearly 30 percent of the IPOs completed were done for companies held in the portfolios of buyout funds such as KKR that were using the IPO as a way to begin to sell their holdings in the company. KKR, the Blackstone Group, and other such firms also turned to Wall Street to raise capital to finance their leveraged buyouts; as the buyout industry's deal making exploded, so did junk bond issuance. In 2000, the average junk bond deal brought in a mere $881,300 in fees for its underwriter; by 2007, the average deal was worth $2.45 million to bankers. In 2005, the year that Vaselkiv and Giroux made their pilgrimage to JPMorgan Chase in search of leveraged loans, those transactions—nearly a thousand of them across Wall Street as a whole—generated an average of $3.5 million in fees.[1]

Only later, in revisiting the events of the decade while testifying to the FCIC, would Nils's ultimate boss, Jamie Dimon, concede that the bank got carried away. "We should have been more diligent when negotiating and structuring" leveraged financing commitments for clients, Dimon said, referring to those loans themselves. "We allowed the lending terms to create too much leverage and assumed too stable a market appetite for these types of loans." Or perhaps they were simply targeting those leveraged loans at the wrong part of that market? But then, back in 2005 and 2006, the buyout funds seeking the leveraged financing, and the hedge funds that bought the CLOs containing the loans, were the bank's biggest clients. Why would that change?

"Let's face it, if you asked J.P. Morgan or Goldman Sachs who their best and most profitable clients were in 2006 or 2007, well, the answer you'd get wouldn't be Lockheed Martin or General Electric," says the manager of one large hedge fund. "The names you'd hear would be KKR or Citadel. Because how many deals or different kinds of deals is a Lockheed going to do in a year? Whereas KKR, well, they do a deal and they'll be back in a few weeks to do another one." And underwriting the junk bond and leveraged loan issuance to finance those deals was just the tip of the iceberg by that point. In addition to those fees, a private equity fund could generate bridge financing fees, deal advisory fees, and,

down the road, IPO fees when the buyout firms exited their portfolio companies (at a profit). In between, there was plenty of opportunity for an investment bank to step in and grab a few million more in fees here and there, in exchange for advising a buyout portfolio company on how to pay out a special dividend to its new owners (a quick way for the latter to book a return on their acquisition) and then for executing that transaction.[2]

Hedge funds, it was also clear by the beginning of the new millennium, could generate similarly lucrative fees for Wall Street in exchange for different products and services. These "go anywhere, buy anything" investment vehicles had become increasingly popular during the 2000–2002 market slump, and their assets under management exploded from the late 1990s onward, despite the collapse of hedge fund Long-Term Capital Management. By 2007, a study by Greenwich Associates, a consulting firm, showed just how important they had become to Wall Street. Hedge funds, unlike mutual funds, usually weren't long-term investors looking for steady sources of return; rather, with hedge fund managers pocketing their fees (20 percent of every dollar of profit earned goes straight to the fund's managers) at the end of every year, they preferred short-term gains and didn't care how many trades it took to earn those returns, as long as the turnover didn't erode returns.

Although hedge funds made up only about 20 percent of all buy-side assets under management (other players included pension funds, college endowments, and mutual funds such as T. Rowe Price), Cambridge Associates calculated that the group was responsible for nearly a third of all trading in the bond markets by early 2007, double the level of only a year earlier. That meant that hedge funds were generating a disproportionate amount of the fees Wall Street trading desks were earning. (Vaselkiv's pledge to be a buy-and-hold investor of leveraged loans was probably the last thing that any Wall Street firm involved in trading wanted to hear.) They were even more important to Wall Street in the smaller parts of the bond market, areas where the market is less liquid and trading harder to do, meaning that investment bank trading desks

could command higher fees for facilitating those trades. Cambridge Associates reported hedge funds accounted for 55 percent of the trading in both investment-grade derivative products and bonds issued in emerging markets.[3] When it came to distressed debt and derivatives with low credit quality and high yields, hedge funds ruled the roost, accounting for 80 percent to 85 percent of the trading volume.

No wonder, as Greenwich Associates pointed out, that Wall Street was now trying to devise products that would appeal directly to hedge funds. The leveraged loans that Vaselkiv had been eyeing were the result of the Street's efforts to attract not one but two important new constituencies: the buyout firms, who needed to issue them to finance their deals, and the hedge funds, who found the loans interesting and profitable to buy and trade. Nobody really needed Mark Vaselkiv.

Turning Wall Street on Its Head

At times, it almost seemed to some bankers that private equity funds and hedge funds had been sent to them by the gods of finance to meet their insatiable need for fee income. Why would anyone be at all surprised that hedge funds were getting red carpet treatment? wonders Leon Cooperman, a former Goldman Sachs partner who set up his hedge fund business, Omega Advisors, back in 1991. "It's like Willie Sutton said when he was asked why he robbed banks—that's where the money was. Why did Wall Street get all excited about this business? That's where the money was!"

Certainly, Cooperman wasn't surprised to see Wall Street begin to tweak its business model to better accommodate these new and very lucrative clients. Investment banks, led by Bear Stearns and Goldman Sachs, packaged up all the services that hedge funds needed under the umbrella of new, dedicated teams that were known as prime brokerage groups. (The name of these groups came from the idea that it made sense for a hedge fund to have one "primary" banking relationship: to rely on one bank for services

such as tracking its positions, monitoring its collateral, clearing, and other services.) Most of the largest investment banks, led by Goldman, JPMorgan Chase, Citigroup, and Morgan Stanley, also created sponsor groups. These teams of generalist bankers were dedicated to serving buyout funds with whatever they needed to put a deal together, coordinating all the specialist bankers and financial wizards who could structure deal terms.

In the early 1990s, very few investment banks had prime brokerages; by 2000, they were ubiquitous and nearly as many had sponsor groups working with their buyout fund clients. Now that the banks didn't make these big private equity clients run from one industry banking team to another, depending on whether their next deal involved an industrial conglomerate or a new computing venture, they could vie for the loyalty of this attractive group of clients more effectively. "There was a need," explains Tom McNamara*, who works as a midlevel banker at one large bank's sponsor group. "The day-to-day business of these guys was doing deals. Serving them is going to be different from serving a widget maker who is only going to do a deal once a decade. There's a big difference between a widget maker's strategic deals and the opportunistic ones that a sponsor will do."

Ever since the 1980s, Wall Street had been in the habit of paying more heed to the needs and wishes of investors than to those of the widget makers on the other side of the transactions that it helped to execute. "It was, has always been, and always will be a case of he who pays the piper the most gets to call all the tunes," says former Morgan Stanley banker Lou Gelman. The pattern was set when Michael Milken priced junk bond deals in a way that rewarded his group of dedicated investors rather than the companies that needed to raise capital; companies were just pleased to have been able to complete the financing. The logic behind this buy-side power was solid: there were relatively few specific deals that a mutual fund manager or pension fund manager had to buy; companies such as Netscape or Google were the exceptions that proved that rule. So while companies trying to raise capital needed their Wall Street underwriter slightly more than the latter needed them, the same

wasn't always true of money managers. Wall Street couldn't annoy a Fidelity, or even a T. Rowe Price, without feeling some pain down the road. "It was very critical to have a very high market share in those institutions, because 80 percent of your business was being done with 20 percent of your clients," says Rob Kapito, president of BlackRock.

Right up into the 1990s, it was firms such as T. Rowe Price that were still paying the piper and calling the tune. That's one reason so many of the IPOs of that decade were priced with plenty of room for the price to pop a few dollars on the first day of trading. When that happened, it was an instant winner for the investors who had just paid $15 a share to acquire the stock in the IPO, and who could now sell it for $18 or so the next day, a strategy referred to as a flip. That was great for buy-side clients, but, as noted earlier, at the height of the dot-com boom it left more than a few of the companies feeling as if they had accidentally handed a cabbie $50 on a $10 fare, and not been offered any change.

The buy-side client—the investor—was the Wall Street client who was there day in and day out, generating fees for investment banks through their trading. Even before the days of hedge funds, the buy side knew how to throw its weight around: a company such as Fidelity wouldn't even promise to hold on to newly issued stock for any length of time, reserving the right to flip some of their shares in a particularly successful IPO for a quick profit. So when Wall Street investment banks began bending over backward to keep the new group of power players—hedge funds and private equity funds—happy, no one was too surprised. But these power players were different. Often run by former bankers and traders, they were really part of Wall Street itself, and had developed business models that relied on deal making alone to generate profits. Buyout firms were consuming capital not to make cars or finance biotechnology research but to acquire companies that they would try to resell for a profit later on. Hedge funds weren't investing the retirement savings of the average American citizen for the long haul but instead were trying to make as many quick bucks as possible. These were more than just new names: they were an entirely new breed of client who

knew how to extract every ounce of value from Wall Street. "You knew when you were sitting across the table from a [buyout firm executive] that you are about to negotiate with someone who used to be a banker," says McNamara. "And you know that his repeat business is going to be so valuable to the next guy on his list that you'll do whatever it takes to accommodate him."

Jeff Arricale, a T. Rowe Price portfolio manager who invests in financial stocks such as insurance companies and investment banks for the firm's mutual funds, understands this trend intellectually. But that doesn't mean it's easy to cope with. "The investment banks know very well that we're never going to call them up and say, 'Thanks, you did a great trade for me, here's a check for $50,000,' " he says, laughing at the very idea. "But a hedge fund manager will do just that—and be back the next day for more. And to get hold of that guy, the dude on the trading desk at Goldman or Morgan Stanley or wherever just has to make a single phone call." In contrast, getting a T. Rowe Price portfolio manager to act on a trading idea might require multiple phone calls and a lot of patience and effort on the part of the Wall Street trader. "Realistically, what we might pay him months later would never be enough to get this guy promoted," Arricale acknowledges. "We keep a close eye on those expenses." In contrast to hedge funds, firms such as T. Rowe Price are doing all they can to reduce their reliance on Wall Street and its endless demands for fees, building their own trading desks and research divisions.

So the fact that with each year that passed Wall Street was paying more and more attention to its hedge fund and private equity fund clients was little more than the financial markets version of Henry Kissinger's realpolitik, akin to the former secretary of state's decision to open diplomatic relations with Mao's China. That kind of pragmatism is what Wall Street is all about, and T. Rowe Price's managers understand and accept the logic that led Nils at JPMorgan Chase to reject them out of hand as potential investors for the leveraged loans. What did worry them was the combination of the nearly monomaniacal focus by Wall Street investment banks on their Wall Street clients and the investment banking industry's

constant need to boost revenues and profit margins. If carried to extremes, this could mean that Wall Street's role as the money grid would take a backseat to the pursuit of profits for their own sake.

Increasingly, Wall Street's newest products fit the needs of the banks issuing them or the Wall Street players, such as the hedge funds, that bought most of them. Many mutual funds didn't want to touch some of the securities that Wall Street was devising; unlike classic bonds, the new products didn't have terms that required the issuer to maintain certain minimum credit standards. In some cases, the company issuing the bonds had the option to finance its regular interest on that debt by issuing more debt, a feature known as a pay-in-kind option and about as appetizing to a mutual fund manager as a dose of cod liver oil. (Indeed, by mid-2008, rating agency Standard & Poor's was already predicting that investors in these securities were likely to recoup only 10 cents on the dollar.) And how, critics wondered, could ordinary individuals saving for retirement be considered logical buyers of highly structured CDOs? By 2007, however, Wall Street firms such as Bear Stearns and their hedge fund partners—firms such as Highland Capital Management—had begun spinning off some of the least attractive CDO structures in products aimed at just those mom-and-pop investors, hoping that they would overlook the warning signals contained in the prospectuses.[4]

Meanwhile, mutual fund managers such as Arricale could see deals in which they did want to invest going to other, more favored Wall Street clients. "There was a company whose stock we had owned for four or five years; we were the third-largest shareholder," Arricale recalls. "They came back and raised more equity through a follow-on stock offering, and obviously we wanted to participate. Then we get the call from the underwriters telling us, 'Congratulations, you got 6 percent of the shares you requested.' And you know in your heart that wasn't a good deal for anyone except the bankers."

Arricale insists that he doesn't feel entitled to stock in deals he likes. "But when I saw the list of where the new stock went, and saw that nearly all of the top ten accounts on that list were the

names of hedge funds, well, there's no way that's in the issuer's interest, either," he says, thumping his desk with his fist. "Come on! This is a hedge fund! What are the odds they'll be around in four weeks, much less four months or four years? They're looking for a quick flip! But they're also the guys waving the big stick. Not only do they generate the trading fees, but if they don't get what they want, they'll move all their prime brokerage business over to Lehman Brothers."

Working on stock underwritings and other corporate finance transactions at a series of investment banks, Peter Blanton found that his corporate clients weren't any happier about this trend. Often he'd have to break the news to clients that even if they didn't want hedge funds to end up as their biggest shareholders, there wasn't much that he or they could do about it. "The clients would tell me, 'I just want the [buy-and-hold] guys, like the mutual fund managers or the pension funds,' " says Blanton. "But the hedge funds were making their way into the new issue market as buyers, and that was just reality." Hedge funds came to completely dominate the market for convertible securities, in particular, thanks to the special characteristics of these "converts." A convertible security is faster and easier to sell to investors than stock; it looks like a bond (because it offers regular interest payments), but down the road investors can exchange it for shares at a set ratio of so many shares per $100 convertible security. Those features—the income and the ability to swap it (convert it) for stock—make convertible securities particularly intriguing to hedge funds. With their trading expertise, hedge fund managers could place complex but profitable bets involving both the convertible security and the stock; the most common of these arbitrage strategies involved selling the stock short. Owning the convertible securities gave them an indirect stake in the company's stock; selling the stock short outright was simply a way for the hedge fund to manage its risk and maybe capture a bit more profit.

But companies that had issued convertible securities in order to raise new capital weren't happy about the unintended consequences. They didn't want hedge funds to buy these securities

if it meant that the funds' next move would be to sell the company's stock short. After all, an increase in short selling not only put downward pressure on the stock price but was tantamount to a public declaration of lack of faith in the company's business or prospects; only very well-informed or sophisticated investors would figure out that the short selling had nothing to do with a lack of confidence and that the hedge funds were merely hedging the exposure associated with owning the convertible security. "There was a period where we'd have to soft-talk the issuer, point out that they'd need hedge funds" to make the deal a success, Blanton says. It took time for the companies to accept the inevitable, although the fact that hedge funds were willing to accept lower interest payments and to quickly commit their capital to a deal helped; companies could now raise capital more rapidly and cheaply.

In the eyes of Wall Street, classic buy-side managers such as Arricale, Vaselkiv, and Giroux were small fry compared to buyout and hedge funds, nitpicking over trading fees and increasingly trying to squeeze already razor-thin trading margins even more. These mutual fund buyers that companies claimed to want as investors could take days or weeks to commit to a deal. Wooing them also meant taking the underwriting client on a four-day road show to visit key investors in cities such as Boston, Baltimore, and Los Angeles in person, an expensive and time-consuming proposition. Why bother, irritated investment bankers wondered, when the hedge funds were willing to just sign on the dotted line?

"Wall Street got to the point, eventually, where it figured it didn't need Main Street, except for the firms like Merrill Lynch, which could use their retail networks as a way to get products out the other end," muses Harvard Business School's Sam Hayes. Although his students have included some of the biggest architects of the buyout and hedge fund universe—including the late Bruce Wasserstein, Joseph Perella, and the Blackstone Group's Stephen Schwarzman—Hayes isn't blind to Wall Street's errors of judgment in catering too slavishly to this group. "There's a kind of social contract that is implicit in the relationship between Main Street and Wall Street," he argues. "Wall Street has to produce a sense of

financial well-being in the shape of a rising stock market, or it will generate a terrible sense of envy [on Main Street] of what will be seen as the obscene profits and compensation that Wall Street is earning for catering to these other groups who aren't seen as part of Main Street."

Dealogic data show that by 2005, when Vaselkiv and Giroux called on Nils, about a quarter of Wall Street's investment banking fees were coming from private equity deals, while 40 percent of the trading fees Wall Street institutions were earning came from executing trades for hedge fund clients. By some estimates, there were now more than eight thousand hedge funds in existence, double the number of only five years earlier, and their managers were in charge of more than $1 trillion in assets, more than three times the level estimated five years previously. Both hedge funds and buyout funds had been important Wall Street clients since the 1980s—firms such as KKR and Blackstone on the private equity side and hedge funds run by veterans with impressive long-term track records, such as George Soros and Julian Robertson. But by the dawn of the twenty-first century, these players were not only more numerous but more significant. Wall Street, in the form of these entities (most run by former bankers and traders), had become its own most important customer, generating the lion's share of investment banking fees and using that influence to even dictate the shape and nature of the transactions that were done.

"In 2003, when I started my MBA program, everyone in the class wanted to be in mergers and acquisitions when they graduated," McNamara says. "By the time we finished, everyone was eager to work for a sponsor group or, as a second best, the prime brokerage group." Today, thanks in part to the havoc wreaked by the toxic combination of cheap capital, innovation run amok, and overaggressive deal making by a Wall Street that had forgotten its traditional client base, McNamara admits that he and other bankers just want a job—any job at all.

Leaving Goldman Sachs?

With the benefit of twenty-twenty hindsight, one can identify the first sign that a fundamental change was in the making. That was the year that thirty-six-year-old Kevin Conway turned down the offer to become a partner at Goldman Sachs, becoming only the second person to do so in the firm's 125-year history. Goldman had been confident enough that Conway would join the partnership to include his name in the list of all the new partners in a newspaper ad. But two days later, Conway left egg on the face of Goldman's management when he announced that, rather than take up the partnership, he planned to leave the investment bank and join the ranks of buyout firm Clayton, Dubilier & Rice.

The gossip spread like wildfire. Turn down a partnership at Goldman Sachs? That was akin to deciding that you'd rather stay in the minor leagues than take a job as a starting pitcher for the New York Yankees. Who in his right mind would do such a thing? Contemporary newspaper accounts explained the move as a result of Conway's concern about the personal risk he would be assuming in becoming a partner at any investment bank: joining the partnership at Goldman, which wouldn't go public for another five years, meant that Conway, like his peers, personally would take on a share of the firm's liabilities. But that had never frightened anyone away before; after all, partnership had almost invariably proven to be a ticket to the top of the investment banking world, and to wealth.

But 1994 was a bumpy time in the financial markets, one of those years that proved life on Wall Street wasn't always a bed of roses. A series of surprising and surprisingly large interest rate hikes in the early spring and summer had wreaked havoc on financial markets; later in the year came a crisis in emerging markets that culminated in the devaluation of the Mexican peso. Goldman Sachs partners were defecting at a record rate—by the end of the year, about a third had left for greener pastures. But Conway's decision still astonished Wall Street. It was one thing to leave Goldman and go off to do something else—politics, say, as Bob Rubin had done and Jon Corzine would do later, or philanthropy. It was also

understandable and acceptable to move on to start a new business, as Leon Cooperman had when he launched Omega after retiring as chairman and CEO of Goldman Sachs Asset Management. But to curtail a career at Goldman so early on, voluntarily, in favor of moving to a private equity firm? Wall Street gave an almost visible shudder of alarm.

For most of the Street's existence, investment banks had been admired and respected institutions; the young bankers who got a toehold on the bottom rungs of the ladders at the top-flight firms were envied by their peers who had to settle for a regional or second-tier firm such as Jefferies & Co. Premier institutions such as Goldman Sachs had become career destinations in their own right. But Kevin Conway's decision to bolt from an elite firm and go to a private equity firm, of all things, would signal the beginning of the end of Wall Street's ultra-elite status. Increasingly, for the Kevin Conways of Wall Street, working for a top investment bank was no longer an end in itself but simply a stepping-stone to something still better. And what was better? In the eyes of aggressive young bankers and traders, more and more that was defined as working for an elite private equity firm (KKR, say, or Blackstone, or even Clayton, Dubilier) or joining a top-flight hedge fund.

By the new millennium, the goal was to be the next Eric Mindich. Mindich was Wall Street's version of Doogie Howser, the lead character in a television comedy whose plot revolved around Howser being both a normal teenager and a genius who, before he gets his driver's license, has already become a surgeon. After becoming the youngest partner at Goldman Sachs in that firm's history (at the tender age of twenty-seven) in the same year that Kevin Conway departed for the world of private equity, Mindich stuck around at Goldman for another nine years before leaving to start his own hedge fund based on the risk arbitrage tactics that he had learned at Goldman (in the group formerly headed by Bob Rubin). Mindich raised what was then a record of $3 billion for a start-up fund, despite his insistence on relatively onerous terms: to get access to the fund, his limited partners had to be willing to tie up at least $5 million of their capital for nearly five years (at a time

when investors in most funds could get their capital back on a few weeks' or months' notice).

Mindich became what all savvy young traders want to be—a multimillionaire who hangs his hat in a Park Avenue co-op building with neighbors such as newsman Mike Wallace. Certainly Mindich couldn't have done that well that quickly toiling away in the (relatively) bureaucratic world of Wall Street. In 2007, his personal share of his new hedge fund's profits was nearly three times what his former boss, Goldman Sachs CEO Lloyd Blankfein, took home—about $200 million, compared to Blankfein's $68 million in salary and bonus. And Blankfein was Wall Street's most richly paid CEO ever that year.

As the years passed, former Morgan Stanley banker Lou Gelman observes, "The best people tended increasingly to see Wall Street as a great place to learn and to forge relationships, and then to leave." (Gelman himself bolted for the hedge fund world in the late 1990s.) "Wall Street, instead of being the folks cracking the whip in the relationship with everyone else, would become more and more under the control of these new Wall Street clients. You just couldn't afford to say no to them." Perhaps not coincidentally, it was also in 1994 that Goldman set up its own dedicated sponsor group to serve the buyout funds.[5]

The increasing prominence and, ultimately, dominance of both hedge funds and private equity funds can be traced to the concept of alpha. In finance, the Greek letter becomes a word that signifies an investment return that is due only to the manager's skill rather than to what the broader market is doing. A portfolio manager who earns 11 percent in a year when the major stock indexes are up from 10 percent to 12 percent is said to earn a return that is mostly beta; she is benefiting from the rising tide of the markets lifting all the portfolio managers' boats. But in a year where an index is up only 5 percent and a manager succeeds in posting a 15 percent return—or whenever the broader markets post losses but an investor generates a positive return—that is alpha. And by the end of the 1990s, the pursuit of alpha made the quest for the holy grail look like child's play.

Investors of all stripes, it turned out, were in dire need of alpha. The biggest among them—pension funds such as CalPERS, the behemoth that oversees the retirement savings of California's state employees, or Yale University's endowment—were run by managers whose all-encompassing goal was finding a stable, steady source of investment returns not tied to what stocks and bonds were doing in any given calendar year. In search of investments that would zig when the U.S. stock market zagged, these powerful players had begun investing in emerging-market bonds, timberland, Chinese stocks, oil well partnerships, real estate in Dubai, and commodities: they were all in quest of alpha returns. Every stock market slump—in 1987, in 1989 and 1990, again in 1994, and briefly but violently in 1997 and 1998—reinforced the importance of having exposure to assets that didn't behave the way the broad market did. The larger and longer-lasting three-year bear market of 2000 to 2002 was when hedge funds, for instance, really caught fire: during that period, their number jumped more than 25 percent, while their assets under management surged 42 percent. While mutual fund managers struggled, many hedge fund managers continued to post positive returns. Hedge funds had an edge over many other "uncorrelated" investments—in contrast to, say, five hundred acres of farmland, the investment in the hedge fund was liquid (at least initially) and relatively easy to value. If an investor wanted to leave, all he had to do was request his money back at the prevailing market value. (As hedge funds became more powerful, however, managers followed Mindich's lead by imposing more onerous lockup periods that meant that liquidity proved more illusory in practice.)

For investors, the allure of hedge funds lay in their go-anywhere approach to financial markets. Their name implies that these managers spent their time hedging, or finding ways to limit the risk of one investment by taking another market position. (One example

of a hedge might be investing in the stock of a company that makes most of its money producing crude oil; to address the risk that a slump in crude oil prices will hurt the stock, an investor might sell crude oil futures short. If crude falls, he would hope to make up in profit on the oil futures what he would lose on the stock bet.) In practice, the thousands of hedge fund managers today pursue far more varied and complex strategies than simply hedging. Some structure complex positions revolving around actual or potential merger transactions involving public companies, shorting one company involved in a deal while owning the stock in another, a strategy known as merger arbitrage or event-driven investing. Others use convertible securities, which combine elements of stocks and bonds, and employ different strategies to capture any difference in value between these and the stock of the company that had issued them. Increasingly, a hedge fund manager was simply an investor who acknowledged no restrictions on where he could invest, how much he could borrow to try to magnify his returns, the extent to which he could use derivatives, or how much he could put to work in a particular stock or industry.

This go-anywhere, do-anything approach was appealing to investors, who felt that skilled managers able to anticipate twists and turns in financial markets should be able to use whatever products and strategies were available to make money regardless of what asset class was winning. Relative outperformance was appealing only in a bull market. Who wanted to own the best large-cap mutual fund in a year when stocks as a whole were in the doldrums? As the Wall Street saying has it, you can't eat relative returns. While mutual funds were restricted to buying, owning, and later selling a specific kind of stock (say, small-cap value shares), a hedge fund manager could do anything he wanted with his investors' money, as long as he spelled out his general strategy in advance. He could invest at home or abroad; he could focus on stocks, bonds, or more exotic instruments; he could buy and hold or sell short; he could borrow to buy and generate leveraged returns; in short, he could be a real master of the financial universe.

"The first time you saw this pattern develop was in the

commodity trading advisor [CTA] world during the eighties," says Glenn Dubin, cofounder of Highbridge Capital, a hedge fund empire that he and childhood friend Henry Swieca built and later sold to JPMorgan Chase. (Dubin and Swieca still run the show.) In the mid-1980s the two partners teamed up to create a series of portfolios combining CTA multistrategy funds with funds that invested in stocks and bonds. "The first big eye-opener for investors probably came during the 1987 crash," Dubin muses. "Soros, [Bruce] Kovner, and all the other guys who were short stocks and long bonds when that happened made a killing, while the long-only guys got pummeled."

Then in 1990 came the first Gulf War; that and the recession that followed seemed to prove that hedge fund managers could make money from anything, in any environment. "You could [own] crude oil futures in the months leading up to the Gulf War, as the supply fear drove prices higher, then short it when the guns started going off, for instance," says Dubin. "Suddenly stocks are plunging and traditional asset managers are losing their shirts, but the global macro hedge fund guys like Soros and Paul Tudor Jones and Kovner are all up enormously as a result of their positions."

The "lost decade" for stock and bond market investors in the first part of the new millennium just confirmed that hedge funds provided alpha, in the eyes of some data providers. The Hennessee Group, one of those market analysis groups, proclaimed that while the S&P 500 Index had plunged 23.33 percent over the course of the ten years between January 2000 and December 2009, the Dow Jones Industrial Average had lost 9.3 percent, and the NASDAQ Composite Index had nosedived 44.24 percent, its proprietary hedge fund index had gained 88.3 percent in the same period. Skeptics may point to the flaws associated with performance tracking in the hedge fund industry, such as survivor bias, but to advocates of alternative investments, results like that spelled one thing: seeking alpha in the form of alternatives, like hedge funds, is the way to go.

By the time hedge fund managers were attracting widespread attention, private equity funds were already well established. One

of the first firms into this new business was KKR. As a corporate banker at Bear Stearns in the 1960s and 1970s, Jerome Kohlberg devised debt-financed exit strategies for small to midsized family-owned companies, deals he referred to as "bootstraps." When Bear Stearns was reluctant to give Kohlberg and his protégés Henry Kravis and George Roberts the capital to establish an in-house fund dedicated to these new transactions, the trio bolted to form KKR in 1976.

The rest is history. KKR landed its first institutional investor (an Oregon state employee pension fund) in 1978, and by the mid-1980s the partners were conducting multibillion-dollar management buyouts of companies such as Safeway and Beatrice. The battle royal for ownership of RJR Nabisco in 1988 proved to Wall Street just how attractive private equity clients could be; the $31.1 billion deal, the outcome of a titanic battle between KKR and a rival group led by RJR Nabisco's CEO along with an investment bank, earned the numerous Wall Street firms involved an estimated $1 billion in fees.

Both private equity funds and hedge funds raised funds privately, from what regulators like to call "accredited investors" and what the rest of us tend to refer to as rich people and sophisticated institutional investors. In other words, unless you have at least a million or two in investable assets (realistically, much more, since even the smallest of these funds likely won't even take your phone call unless you're worth $15 million or more and can spare at least $1 million for their fund), don't bother trying to get inside the golden circle. Investors, referred to as limited partners, tie up their capital in a private equity fund for a decade or so. In the early years of a fund's life, its general partners (the managers at funds such as KKR) spend their time hunting for deals and investing and then find ways to exit at a profit. (As of this writing, KKR has raised about fourteen different private equity funds over its life span.)

The long-term secular decline in interest rates throughout most of the 1980s and 1990s fueled a boom in the leveraged buyout business, making financing relatively cheap and helping private equity funds reward their investors with outsized returns. By mid-

2008, KKR estimated it had invested about $43.9 billion and earned $60.1 billion in profits from those fourteen funds; another $27.5 billion of profits were still on paper because the investments hadn't yet been sold. It also revealed that its average annual internal rate of return (IRR, the most commonly used measure of investment returns used by private equity investors) was a whopping 26.2 percent during a period when investing in the Standard & Poor's 500 index would have earned the same investors about 8.8 percent a year.[6] With that kind of track record, it was little wonder that investors didn't balk at the fact that it could take years before KKR and other buyout funds would achieve those returns and pay them their share of the profits. In fact, while once investment managers who had run portfolios stuffed with illiquid assets that couldn't be quickly sold for a price close to their fair value—like those of a private equity fund—charged their investors lower fees to compensate for the lack of liquidity, now the magnitude of those returns (all that alpha!) meant that firms such as KKR could command premium fees. While a mutual fund might charge a flat 1.25 percent management fee, KKR could levy a 2 percent fee—and collect 20 percent of any profits, to boot. In the eyes of investors, illiquidity was no longer a risk, but simply the price one paid for alpha.

Hedge funds adopted a similar compensation scheme. But while private equity investors didn't get their 20 percent share of the profits until after the investments in their portfolios were sold, hedge fund managers could become very wealthy very quickly through what is known as mark-to-market accounting. At the end of every fiscal year, the assets in the hedge fund are valued, and the manager typically pockets a fee equivalent to 20 percent of those paper gains without having to liquidate the portfolio. (That compensation scheme is, in the eyes of some private equity investors, responsible for some of the aggressive risk taking on the part of hedge funds; as long as the transaction worked in the short run, hedge fund managers could become wealthy regardless of what happened to their investors over the longer haul.) By the mid-1990s, the prospect of easy riches enticed a steadily growing

procession of bored, frustrated, or fed-up traders to walk away from their investment banks and set up shop on their own.

At first, explains Patrick Adelsbach, a principal at Aksia, a hedge fund advisory group, who has studied hedge funds since the early 1990s, these traders invested their own money, the fruits of years of big bonuses, and brought in some family and friends as fellow investors. Those who were successful quickly earned a reputation as stars and went on to establish a more formal structure. By 2000 or so, skilled traders with an idea for a new niche strategy were leaving investment banks at a rapid clip to set up their own shop; Goldman's IPO in 1999 spawned a particularly large batch of new hedge fund managers, including, ultimately, Eric Mindich. "It seemed almost as if these guys were afraid of being left out of the biggest party around if they didn't leave and start a hedge fund," says Anna Pinedo, a partner specializing in securities law at Morrison & Foerster, a national law firm. With each year that passed, the new funds became larger; in the late 1990s, a significant debut fund could have $100 million to $200 million in assets, but by 2002 or so, a manager needed to have $300 million to even get the attention of Wall Street's traders and the burgeoning prime brokerage industry.[7]

Wall Street had long recognized the potential for hedge funds to become a big new source of fees. Bear Stearns was one of the first, using its expertise in the relatively unglamorous business of clearing trades (making sure that they are properly executed and documented) to move up the food chain and provide other services to hedge funds, including record keeping and lending them the stocks they needed in order to sell short. Other firms caught on quickly; by the early 1980s, Morgan Stanley was providing one-stop shopping for Julian Robertson's Tiger Fund as well as for George Soros, while Goldman Sachs dealt with the needs of another top hedge fund manager, Michael Steinhardt, within what was known as their personal client services division. These ad hoc services formed the basis of the prime brokerage groups.

The earnings power and clout of Goldman's new prime brokerage business, Global Securities Service (GSS), grew in tandem

with the hedge fund industry itself. The business was so profitable that soon employees in GSS without MBA degrees were outearning those who did possess the coveted degree but who toiled away in higher-profile but less profitable parts of the firm.[8] The good times only got better in the coming years as the hedge fund industry's explosive growth continued, peaking at 9,550 funds managing a cool $1.535 trillion in assets by mid-2007. Best of all, because hedge funds needed the services so much—and were raking in so much money in management and incentive fees—they didn't balk at paying the bill for prime brokerage services. Finally, it seemed, Wall Street had found a product that couldn't be easily commoditized and that maintained its profit margins. Despite the growing competition from the mid-1990s onward, Goldman Sachs, at least, found that its prime brokerage fees slid a relatively modest 20 percent, an amount it could easily recoup from the massive growth in volume.[9]

Using these new prime brokerage businesses, investment banks set out to do everything they could to smooth the path for traders hoping to launch a hedge fund, facilitating the industry's explosive growth. "The average bank had a turnkey solution for any manager who wanted it; he'd show up at one of the more sophisticated prime brokers like Goldman or Morgan Stanley, and the guys there would find him office space, help him set up his computer technology, even help him order his office furniture," says Adelsbach. They'd also introduce the fledgling manager to potential investors, offering what they dubbed "capital introduction services." (Among the beneficiaries was Galleon, the now-defunct hedge fund group whose CEO was convicted on insider-trading charges in mid-2011: Goldman offered its assistance in meeting potential investors.) The pitches walked a narrow line between what was legal and ethical and what wasn't; funds would be invited to attend high-profile conferences where they could set up booths in the exhibit halls or brokers would help a new manager arrange a series of meetings with potential investors. The very fact that Goldman or Morgan Stanley was willing to stamp the Wall Street equivalent of a Good Housekeeping seal of approval on a start-up hedge fund was

enough to set the new manager apart from the crowd. The tacit quid pro quo was that the manager would direct all his trading and other prime brokerage business to the firm that employed his capital introduction team.

The stock market slump and the economic recession that followed the collapse of the dot-com bubble in 2000 rang the death knell for old Wall Street relationships. As they had in past slumps, hedge funds outperformed the stock market during its three-year slide (in their worst year, 2002, the average fund fell only 2.89 percent).[10] Unhappy investors pulled money out of the stock market and directed it to the portfolios run by the go-anywhere gurus. Pension funds, facing future payout obligations to retirees and blindsided by large losses, found the allure of alternative asset classes and alpha to be almost magnetic; they hoped hedge fund gains could help them recover their losses as rapidly as possible. The stock market's malaise meant that stock underwriting was difficult and far from lucrative for investment banks; after raising $300 billion in equity for companies in 2000, Wall Street institutions collected fees on a measly $97 billion of deals in 2003.[11] Nor were there many M&A advisory fees to be earned: few corporations were interested in making strategic acquisitions in the midst of economic uncertainty when they couldn't compute the value of what they planned to buy. While the private equity funds weren't immune to the market slump of 2000 to 2002, they still had funds to invest and a big incentive to do deals. KKR alone raised another $6 billion in capital in 2002, a sum that could finance $35 billion or more in buyouts, given how low interest rates had fallen and how easy it had become to obtain debt financing even for risky transactions. But if Kravis and his colleagues didn't put that money to work, they wouldn't even earn the 2 percent management fee.

The "Saviors" of Wall Street

By 2002, it was clear the balance of power had tipped away from

Main Street institutions—investors such as T. Rowe Price and corporations that relied on Wall Street to meet their capital needs—in favor of these new players. "New prime brokers were calling us every day," says Nick Harris*, manager of a large hedge fund. "They were offering us access to their balance sheet—if we needed to borrow to trade or otherwise generate fees for them, well, they were going to do whatever it took to make sure that happened." His fund's average leverage level was around 1.5, meaning that for every $1 billion he invested of the firm's own capital, he would borrow another $500 million from one of those eager prime brokerages and invest it, too. But Harris's prime brokers were urging him to go further, to raise that borrowing to $1 billion. "When I started in the business in the early 1990s, you could lever up three or four times what you had on your balance sheet," Harris recalls, meaning that for every dollar of capital, a maximum of $3 or $4 could be borrowed. "At its most extreme level, leverage of 20 times became at least theoretically possible."

On the surface, borrowing was tempting; it was certainly cheap, since interest rates had fallen and so had the cost to hedge fund managers to borrow. At the end of 2001, Harris says, his interest costs were 170 basis points above the international interest rate benchmark, known as the London Interbank Offered Rate (LIBOR). That meant that if institutions borrowing money on London's interbank market paid 2.5 percent, he would be forking over 4.2 percent. By 2005 or 2006, he says, those costs had plunged to 30 basis points above LIBOR; a 2.5 percent LIBOR rate would have meant he was now paying a mere 2.8 percent to borrow the same amount of money. Had Harris increased his borrowing, he would have had a lot more firepower to put behind his trading strategies and investment ideas, making it possible for him to earn exponentially higher returns. But he was also aware that if a trade went sour, the borrowing could backfire.

The Wall Street prime brokers didn't seem worried about that risk and even downplayed it, he says. Of course, the more leverage they could persuade Harris and his fellow hedge fund managers to take on, the higher the fees they could generate for their firm. And

even the ultralow borrowing costs weren't set in stone, Harris says. The prime brokers' original role was handling back office functions for the thinly staffed hedge funds, keeping track of trades, clearing them, and keeping custody of the assets, carefully segregated from those of its other clients. The profit margins on this business might be low, but it was a consistent earner for the prime brokerage. "Our firm alone was large enough that we could generate $10 million to $20 million just in custody and back office fees these prime brokers charged" every year, Harris says. The prime broker also tended to handle a lot of trades for its hedge fund clients, collecting fees on those as well. Those fee streams were important enough in their own right that hedge funds could use them as a way to negotiate even lower financing costs. The more Wall Street firms jumped into the prime brokerage business, "the more we had carte blanche," he adds.

If Wall Street's prime brokerages were helping to drive up the level of risk taking in the financial markets by making ultracheap financing available to hedge funds, its investment banking operations were about to play their own part in making the financial system riskier. Once it had seemed at least possible for an investment bank to take the moral high road and not participate in a deal that might jeopardize the firm's reputation or long-term profits simply in order to capture a fee. That's what Goldman Sachs had done when it chose not to advise corporate raiders and others making hostile takeover bids. But as competition to woo the notoriously fickle private equity firms became fiercer and as clients grew more cutthroat by the day, the investment banks themselves rejected the mere idea of leaving anything behind on the table that a rival might be able to parlay into a penny of profit. By 2006, private equity firms, encouraged by the availability of cheap capital and their ability to raise larger and larger funds from alpha-hungry investors, were doing new deals at such a rapid clip that at any given time, a bank's sponsor team could be working on four or five multibillion-dollar takeovers simultaneously, recalls Tom McNamara.

The deals were sometimes happening so quickly that it was

nearly impossible to conduct proper due diligence. “On a Friday afternoon at 5:00 p.m., Blackstone or someone would call and want a commitment from us to finance a deal that would require $15 billion in debt—and they would want it by Monday,” McNamara says. Credit research was being conducted by associates, the junior members of the team fresh out of business school, because there weren’t enough experienced credit analysts to go around. When something struck one of them as not making sense or being too risky, McNamara says, “the response was that if we didn’t do this, someone else was going to—one of our rival institutions. Then whoever had asked the question would be told, ‘Are you going to be the guy that didn’t get the commitment okayed, and the guy who let that business and all its fees go to a competitor?’ ” Naturally, nobody wanted to be that guy.

The business of financing buyouts proved nearly as addictive as crack cocaine. Banks could collect a series of fees from these private equity funds and didn’t have to spend millions of dollars wooing them or presenting them with deal ideas that would never be acted on, as they did with corporate clients who didn’t do deals for a living. The first revenue might come in the shape of an advisory fee, or in exchange for a financing commitment. Another fee could be levied on providing interim financing or bridge loans. More fees could then be charged for selling the junk bonds and leveraged loans that replaced that interim financing. And then there was the 7 percent fee that the bank could collect on the IPO of the company in a year or two.

Lloyd Blankfein, CEO of Goldman Sachs, admitted that his institution, like others, “rationalized” pushing the risk envelope during the credit bubble years. But he also insists that these rationalizations for the relaxation of lending and credit standards were completely justified. In his January 2010 testimony to the FCIC commissioners, Blankfein says bankers would cite reasons such as the power of the emerging markets and the ample liquidity in the financial system to justify the risk taking. But he undermined his own argument when he concluded that the rationalizations were the result of the fact that “a firm’s interest in preserving and

growing its market share, as a competitor, is sometimes blinding—especially when exuberance is at its peak."[12] In other words, while every other firm on Wall Street may have been chasing Goldman Sachs, Goldman itself was afflicted with just the same kind of hypercompetitive urge, and feared losing even a fraction of a percentage point of market share to its own rivals.

These sponsor-backed IPOs weren't the tiny, $100 million or $200 million deals that came from taking start-up companies public. The IPO of private-equity-backed Hertz, the large car rental company, was a $1.32 billion affair that raised an estimated $90 million in fees for its underwriters—Merrill Lynch, Goldman Sachs, and JPMorgan Chase. Anyone who wanted a piece of those fees down the road had to be prepared to play ball with the private equity funds when the latter first structured and sought to finance those takeovers, says Peter Blanton. Blanton himself wasn't involved in putting together the packages of bridge and longer-term buyout financing, involving multiple layers of loans and bond issues, but he'd hear about them when it came time for the bankers to try to win the lead underwriting job on the IPO. "Writing the pitch books, we'd always note that we put up some of the original money, so we should be part of the deal." That turned into a vicious circle; the next time the same private equity team needed financing for a deal, they'd use the same argument to the bankers: they had just paid out millions of dollars in underwriting fees and so had earned some generous terms on the next financing. "A lot of sponsors looked at Wall Street and saw a honeypot full of money and felt that was their money, because it had come out of their pockets when they paid the IPO fee," Blanton says. "Now they wanted some of that back in concessions on the cost of the deal financing. The Wall Street firms had no backbone; all anyone could say was yes. The answer was never no." Wall Street institutions knew they might be getting squeezed on the terms of any single deal by their ultra-aggressive clients. But they could make up for that on volume, they reasoned.

Some bankers chose not to stick around. Gelman, the Morgan Stanley banker who had helped bring Netscape public even as he

saw it as an example of Wall Street's transformation into a casino that encouraged short-term speculation rather than long-term investing, left early, before the market reached its most extreme levels. He didn't want to go through the whole dot-com experience again, this time with junk-bond-financed buyouts. "Over and over again, I'd find that the client whose stock issues I worked on wasn't a corporation raising capital for a new plant, but an IPO that would get a buyout firm a fast profit," he says.

Private equity funds argued that the way they earned their hefty returns was by taking a poorly managed company private, restructuring and overhauling its operations, and then selling the new and improved version, either back to public shareholders in an IPO or to another private buyer. But the time frame that elapsed between when the buyout was done and the IPO that marked the buyout fund's exit shrank steadily. Often, the private equity managers might have bought the company less than a year before the IPO, not enough time to make any fundamental operational changes, much less for those improvements to pay off in higher earnings or a higher valuation. A transaction like that "was a classic flip," Gelman says. The stock underwriting business, once a craft, had become an assembly line, he laments. "It was all about 'How many deals can we price this week?' " Gelman left, he says, "when it became impossible to be an effective conscientious objector to these deals."

Others stayed but became increasingly worried by the deals that were being done. Some voiced concern about the pattern of one buyout company selling portfolio companies on to another one, a phenomenon that became known as secondary buyouts. Why, they wondered, would a company that supposedly had already been through the private equity wringer—costs slashed, business revamped and refocused—be attractive to another buyout firm, one that presumably would try to make money by doing exactly the same things? If there was any fat left to be trimmed, that meant that the first firm hadn't done its job properly, which meant it wouldn't be able to extract the maximum sale price and thus the maximum return for its investors. On the other hand. if the first firm had done

its job properly, then the second buyer was making a foolish investment; there would be no way for its managers to generate a return for their own investors. Private equity investors were openly skeptical, but the deals got done: by the end of 2004, the Simmons mattress company had been acquired by no fewer than five different buyout firms—the fifth, Thomas H. Lee Partners, had paid $1.1 billion for the company.

Deals, Deals, Deals!

Secondary buyouts were just the tip of the iceberg, bankers and private equity funds agree today. By 2005, dividend recapitalizations had arrived on the scene as a way for buyout firms to generate quick profits on deals they had done only a few months earlier. Think of these as being a bit like refinancing a mortgage: the homeowner takes advantage of the increase in her home's value (or at least the increase in its paper value) and increases the size of the mortgage. While homeowners were doing just that in the mid-2000s, private equity firms did the same with the companies in their portfolio in order to lock in profits for themselves and be able to provide returns to their investors more rapidly.

"What I think happened was that bankers weren't gatekeepers, thinking about the quality of the transactions they were financing for their buyout clients," says Jake Martin*, a partner at one large buyout firm. Investment banks were shuffling the assets they underwrote off their own books as rapidly as possible and into the portfolios of other investors. "The question became not whether it was an attractive deal for buyers so much as 'Is it structured right, so that I can push this stuff out the door?' " A lot of lipstick was being applied to make a lot of pigs look more appealing to buyers, he figures. With interest rates at such low levels, buyout firms had an incentive to put smaller amounts of capital into each deal they did —perhaps 10 percent or even 5 percent of the total value—and finance the rest. That was great news for all concerned. The buyout firms could put more money to work in more deals, and have less

cash at risk in each one; the greater the number of deals done, the more fees the Wall Street bankers could collect. Because investors were starved for securities that offered even slightly higher yields than those on Treasury notes, they held their noses and bought.

Martin admits that his firm was probably one of the beneficiaries of this phenomenon, able to finance its transactions more cheaply than otherwise would have been the case. But he adds that the new dynamics of the market—particularly the fact that increasingly the only investors who would buy the relatively low-yielding and higher-risk debt used to finance the later-stage buyouts were hedge funds—ultimately made his life more difficult. "We would rather know who is going to own our paper," Martin says. "In the old days, you'd know who your lenders were and you'd have a relationship with them, and if something went wrong, you'd go and you'd sit down with them and work it out. Now I go and look at the list of people who hold my paper and it's like alphabet soup. It's XYZ hedge fund, or JJB, or GBX, all weirdly named hedge funds that I've never heard of before. If I have a problem with a company and try to talk to them, they basically look at me as if I'm a criminal, and I can see them wondering, 'What kind of pound of flesh can I get out of you? What extra return from your misfortunes can I get?' That is just the reality of today's Wall Street."

Wall Street Joins the Party

Watching their clients rake in profits hand over fist beginning in the late 1990s, Wall Street firms found themselves envying the apparent ease with which they made money. Serving these clients was great; working with hedge funds meant that they not only earned big fees but also picked up valuable market intelligence that helped in other parts of their business. But across Wall Street, investment banks as well as banking giants such as Citigroup began to wonder how they could capture a bigger slice of the pie for themselves. Wouldn't the best way to maximize profits for their own restless shareholders be to just become their own clients?

A growing number of firms took stakes in hedge fund businesses; JPMorgan Chase's acquisition of Highbridge was the biggest deal, but Morgan Stanley spent $1 billion to purchase pieces of Avenue Capital, FrontPoint Partners, and Lansdowne. Citigroup paid $800 million for Old Lane Partners, a hedge fund founded by former Morgan Stanley banker Vikram Pandit, as part of a bid to convince Pandit to join the company's team of top executives. (That turned out to be a particularly controversial deal when, less than a year later, Citi shut down Old Lane.) Lehman Brothers acquired stakes in firms such as Ospraie Management, run by high-flyer Dwight Anderson, an alumnus of Julian Robertson's Tiger fund. It also backed former employees who decamped to start hedge funds; after all, one of them might become the next star, like SAC Capital's Steve Cohen. Among its other investments, Lehman acquired a 45 percent stake in R3 Capital Partners, started by a former proprietary trader at Lehman, Richard Rieder, as late in the game as the spring of 2008. (By the time that interest was sold in October as part of Lehman's bankruptcy proceedings, it had lost half its value.)

Still, Wall Street CEOs wondered whether it wouldn't be even better if their firms could just go and make money for themselves in the financial markets, using their capital to do deals and place bets in the markets through proprietary trading desks. Why not become

deal makers in their own right? The logic was impeccable: turning themselves into their own client would be so much simpler … and it wouldn't require that much of a leap. Ever since Wall Street had begun its transformation back in the 1970s, investment banks had been looking for ways to put their balance sheets to work profitably. "All Wall Street CEOs have two traits in common," says Marsh Carter, deputy chairman of NYSE Euronext and former chairman of State Street Bank and Trust Corp., who has worked closely with most of the current crop of these individuals. "They are very, very, very optimistic. And they all have an undying, unquenchable thirst to do something unique."

To Pete Peterson, who headed Lehman Brothers from the early 1970s until the early 1980s, unique meant looking back in time to the days when banking meant merchant banking, buying and owning businesses rather than just serving as an intermediary for others. Financing other people's deals was inherently perilous, Peterson worried, since blips in the market or the economy could cause a stream of fees to vanish overnight. Why not use Lehman's capital to do its own leveraged buyouts or invest in other businesses, such as real estate, where no one else put a limit on how much they could earn by telling them what kind of fee was acceptable?[13] Lew Glucksman, Peterson's co-CEO, had a different vision for the firm, however. A street-smart trader, Glucksman was aware that trading the growing array of products available—options, futures, and commodities, as well as stocks and bonds—generated two-thirds of Lehman's profits by the early 1980s.[14] Why shouldn't the firm build on those strengths and put its capital to work accommodating its trading clients and taking proprietary positions?

Both co-CEOs had a vision of the future that went well beyond Wall Street's classic role as an intermediary and involved Lehman using its own capital and becoming its own client. The difference in the nature of their vision, however—Glucksman believed Lehman should become more like a hedge fund, while Peterson preferred a private equity model—resulted in an epic battle for control of the firm in 1983. Glucksman triumphed briefly, ousting Peterson and

ruling the company for another ten months before the partnership collapsed under the weight of the internecine battling. It is perhaps not surprising that Peterson went on to cofound the Blackstone Group with fellow Lehman alum Stephen Schwarzman in 1985, a company that the two men turned into one of the largest buyout firms in the world. (Glucksman went on to work with Sandy Weill as the latter began building what became Citigroup; he died in 2006.)

At Goldman Sachs, partners were also debating how best to make use of their own balance sheet. As Wall Street's transformation got under way in the 1970s and 1980s, a growing number believed that the recipe for long-term survival and success involved more than simply acting as an agent for its clients: Goldman Sachs should do business as a principal, to take risks with its own capital and pocket 100 percent of any return. Steve Friedman and Bob Rubin battled to get their partners' assent to a $5 million investment in one of KKR's first funds over the objections of colleagues who griped that they didn't want their profits going to support the business launched by Jerome Kohlberg, Henry Kravis, and George Roberts. But the investment was made, clearing the way for more direct investments in operating businesses by Goldman itself. Goldman veterans still fretted that this time KKR would see them as rivals instead of bankers. ("Yes, but they'll get used to it," Friedman retorted.) Finally, in 1991, Goldman opened what would become the first in a series of private equity funds carrying the Goldman Sachs brand name.[15] The $1 billion GS Capital Partners I, with $300 million of Goldman's capital invested in it, set out to compete directly with the big guys. In less than two decades, Goldman Sachs was the big guy, raising a $20 billion fund that even dedicated buyout firms such as KKR and Blackstone would find hard to match in size.

Goldman was slower to set up its own hedge fund, although Leon Cooperman had proposed doing so at a partners' meeting in the same year that GS Capital Opportunities made its debut. "The other partners were reluctant, because the hedge fund might short stocks of companies who were also investment banking clients of the

firm," Cooperman recalls. "They worried that if that happened and the clients found out, there would be hell to pay. They just weren't progressive enough to see that in a few years this would become mainstream" and that even though those corporate underwriting clients didn't like it, they didn't have enough clout to punish the increasingly powerful Wall Street institutions. Cooperman left to set up his own hedge fund, to which other Goldman alumni have flocked. Meanwhile, Goldman quickly overcame its qualms and rolled out proprietary hedge funds. It also allocated a steadily increasing stream of capital to its proprietary traders, who were charged with using that money to generate profits for the firm in much the same way that the hedge funds would.

Both the hedge fund and proprietary trading businesses exploded in the 2000s. "Within ten years after I failed to convince them, suddenly hedge funds were all they were selling to their [investment] clients—these premium products," says Cooperman. Indeed, so great was Goldman's dependence on these principal activities—private equity investing, its hedge funds, and its proprietary trading business—that among the cognoscenti it had become almost a cliché to refer to Goldman Sachs as a hedge fund disguised as an investment bank. That's a description still guaranteed to cause Goldman Sachs executives to sputter in outraged indignation. Gary Cohn, the company's president, insisted in a 2009 interview that "the vast, vast majority of our revenue and income comes from our client facilitation" activities.[16] Many see that as posturing; others nod knowingly at the almost Clintonesque precision of Cohn's choice of words in describing Goldman's activities.

Ultimately, it became hard to figure out whether a Wall Street investment bank was operating as an intermediary, helping clients finance transactions; as a partner, investing alongside them; or as their rival, competing with them for trading ideas or access to deal flow. "It became very situational," says Jim Tanenbaum, a partner at Morrison & Foerster, who has worked closely with Wall Street clients of all stripes; the answer would vary depending on what day of the week it was or even the time of dav. If Goldman Sachs met

with the board of directors of a company thinking of going public, there was no guarantee that the investment bank would agree to underwrite the deal, for reasons Tanenbaum says had less to do with the IPO candidate's appeal to public investors than with Goldman's own interests. "What would have happened? Goldman's bankers would have gone to the first meeting, said, 'That's very interesting. Let us introduce you to some of our colleagues,' " he observes. "And then at the next meeting, they'd be there with managers of their proprietary funds, because they had decided that rather than be the conduit for you to raise capital and earn a fee, they'd rather compete with their peers by buying you outright or investing in you." Instead of acting as an agent, the banks had themselves become principals in the financing transactions.

Is that better or worse for the hypothetical company looking for new capital? It's impossible to know if the company would have been better off following the traditional path of going public and selling stock to a number of mutual funds rather than selling itself to a private equity firm. Blanton is forthright in assessing the kind of analysis that was being made by his bosses. "Who is to say that this is wrong? You're a public company; your duty is to make money for your shareholders. And if everyone else is doing it too, why would you be the one firm to become holier than thou? It's just inconceivable." What was significant was that, increasingly, it was harder than ever for midsized or start-up companies with respectable revenue and profit track records to go public. Meanwhile, venture investors and bankers note that the same investment banks who turned them away as underwriting clients would often return with acquisition offers, sometimes emanating from themselves, on other occasions on behalf of buyout funds. Wall Street firms, which once saw their role as facilitating access to public markets, increasingly seemed inclined to block it, say a number of corporate lawyers and venture capital investors.

Part of this shift, Wall Street veterans agree, stemmed from the fact that investment banks and the growing numbers of commercial banks vying with them for capital markets transactions were almost all publicly traded businesses by 2000. Only a handful of firms

remained partnerships, including Lazard, Greenhill & Co. (the boutique launched by former Morgan Stanley rainmaker Bob Greenhill) and Evercore Partners, another boutique launched by a group of veteran bankers (many of them Blackstone alumni) including Roger Altman, who had also worked at Lehman Brothers. (By 2008, all of these firms would also be publicly traded, following an IPO.) "When I started practicing on Wall Street, none of this could have happened, because people owned their own firms," remarks Tanenbaum. "The idea of using capital to pay traders based on the volume of the business they did would have been viewed as an absurdity."

Now that they were publicly traded, investment banks faced two conundrums: the perennial challenge of finding new and profitable business lines in order to deliver a stream of steadily rising profits to shareholders; and finding ways to deploy their constantly expanding balance sheets to generate those profits. "When any company raises new capital, they need to invest it in a business that will make even more money than what they are already doing," says Jimmy Dunne, CEO of one of Wall Street's boutique investment banks, Sandler O'Neill. "It's no good raising capital if it goes into a business at which they aren't as good as they were at the core business. That's a bad use of capital." Not coincidentally, Sandler O'Neill remains a private partnership.

The consequences of the business decisions made by the likes of Stan O'Neal and Lloyd Blankfein—CEOs of investment banks that were now accountable to outside shareholders—were reflected not only in the rate of growth in their profits but also in the kinds of business that were now generating those profits. At Merrill Lynch, revenue from trading and principal investments—the kinds of activities in which the firm used its capital to generate profits for itself, becoming its own client—was 47 percent in 1997, rising to 55 percent in 2007, according to data cited in the Financial Crisis Inquiry Commission's final report. At Lehman Brothers, 32 percent of pretax earnings flowed from these transactions in 1997, compared to 80 percent a decade later; in some years, Bear Stearns generated more than 100 percent of pretax earnings from those

businesses, thanks to losses in other divisions. And at Goldman Sachs—which remained the envy of all its rivals for its ability to steer its way effortlessly through any controversy while turning everything it touched to gold—the proportion of revenues attributable to proprietary trading and investing jumped from 39 percent in 1997 to 68 percent a decade later. As a result, profits for the financial sector, which had made up about 15 percent of all corporate profits in 1980, ranged between 27 percent and 33 percent of total corporate profits in the years immediately preceding the meltdown.

By early 2006, some of Wall Street's more thoughtful insiders were questioning what was happening. How much of the record earnings that investment banks were posting could be attributed to their wisdom and deal-making prowess, and how much to the fact that they were benefiting from record low interest rates and investors' seemingly insatiable appetite for risky investments? What was unquestioned was that by 2006, the definition of success for Wall Street had changed. Once, the masters of the universe were those who could navigate the money grid most adeptly, generating the biggest benefit for their corporate clients while earning hefty fees for their firms. Now success was about not only serving a new breed of clients but trying to emulate them. Financial alchemy was the magic ingredient; if they could find the right ways to structure and hedge their financial innovations, the world, they were sure, could be their oyster.

And killjoys? Well, they didn't last long on the new Wall Street. No one had to look further than Phil Purcell, the Dean Witter executive who had risen to the top spot at Morgan Stanley in the wake of the two firms' merger in the late 1990s, only to be ousted in 2005 in a bloody battle for control of the investment bank. "In a lot of ways, the smartest guy out there was Phil Purcell," comments Nick Harris, the hedge fund manager. "He took few balance sheet risks, he said no to that special bottle of Château Leverage 2003. And he got fired for it."

That was only part of the story, of course. Purcell was widely disliked within Morgan Stanley, and during his time at the helm a

number of top bankers had fled the elite investment bank. Still, under Purcell, Morgan Stanley hadn't taken the same kind of big balance sheet bets as its competitors—and that showed up in the company's profit margins and return on equity, which compared unfavorably with those of rivals. Shareholders were already concerned by news of the defections, and, backed by bankers inside the firm eager to delve further into the world of principal investing and proprietary trading, they ended up ousting Purcell. "He just didn't get what it meant to be a banker in the twenty-first century," says Gelman, the former Morgan Stanley banker. "I don't know why he seemed to be surprised that people weren't happy." Purcell's replacement was John Mack, who promptly went where Purcell had feared to tread. When Morgan Stanley reported its first-quarter earnings in 2007, the company announced a $1 billion profit made by shorting subprime securities in the first stage of their slump; investors beamed with delight at one-upping Goldman Sachs.

The lesson of Purcell's ouster wasn't lost on anyone. It wasn't that people lamented his absence as a person or even as a leader. But to many Purcell stood for an old-fashioned way of thinking about what Wall Street did and how it worked. "His Wall Street was a customer-focused place, not a place where people chased after business as a principal," Gelman notes. So Purcell's departure was symbolic; if he could be driven out of Morgan Stanley for failing to maximize profits at all costs, the thinking went, then consciously walking away from business opportunities just because they might involve a bit of risk was likely to be a career-limiting move for anyone else on Wall Street. "We watched, we listened, and we all learned from that," says another Wall Street veteran. "The message was clear: the question we were supposed to be asking ourselves wasn't whether a piece of business was prudent, it was whether it would help us beat Goldman Sachs."

CHAPTER 4

To the Edge of the Abyss—and Beyond

Flying Too Close to the Sun

Richard Fuld didn't like naysayers or killjoys any better than anyone else on Wall Street, especially when they came from inside the ranks of Lehman Brothers, the firm that had been his home his entire professional life. As CEO, he struggled daily to win the respect he felt Lehman deserved after clawing its way to the position of Wall Street's fourth-largest investment bank. Occasionally Lehman even managed to earn a larger return on equity than Goldman Sachs did, as happened in 2000 and again in 2003. Fuld, say some former Lehman bankers, was obsessively competitive and focused on beating Goldman Sachs on a consistent basis, and that meant emulating Goldman's risk-taking culture and taking on even more leverage. While Goldman Sachs borrowed about $25 for every dollar it put to work in proprietary deals or other high-margin undertakings, Lehman, by some calculations, borrowed more than $30. To continue earning those returns, Lehman devoted a lot of that capital to buying mortgages and repackaging them into CDOs as fast as it could, billions of dollars at a time. The 1 percent fee on creating and selling CDOs was a windfall that flowed straight to Lehman's bottom line.

When Mike Gelband, Lehman's new co-head of fixed income, began questioning the health of the real estate market in the summer of 2005, he was directly challenging the resolute optimism of Fuld and his closest allies at the top of the firm about one of the most profitable parts of their business. According to Lawrence

McDonald, a Lehman banker who went on to chronicle the collapse of the investment bank in a book entitled A Colossal Failure of Common Sense, Gelband was a studious kind of person, as bankers go. But, McDonald added, "to this day I've never met anyone who could grab and comprehend a difficult new idea faster than Mike Gelband."[1] The "difficult new idea" that Gelband was focusing on in June 2005 certainly wasn't a welcome one for many at Lehman. It had nothing to do with the invention of a new way to make money but instead questioned the rationale for the profits the firm was already earning. Gelband prepared a thirty-page report spelling out just why he thought the real estate market was a bubble about to pop and do far more harm to Wall Street and the economy than the Internet bubble had done only a few years previously.

Gelband presented his evidence to McDonald's group early one morning at the beginning of June 2005. To the tense group of bankers and traders assembled in a conference room at Lehman's mid-town Manhattan headquarters, he argued that the real estate industry "was pumped up like an athlete on steroids, rippling with a set of muscles that did not naturally belong there," McDonald later recalled. "Those muscles gave a false impression of strength and in the end would not be sustained."[2] With almost oracular ability, Gelman identified everything that would go wrong and ultimately cost Fuld his post and Lehman its very existence—the rise of the shadow banking system of which Lehman was a part, the leverage, the poor quality of the mortgage loans that Wall Street was churning into CDOs. He even predicted the timing of the debacle: the chickens would come home to roost in 2007 and 2008, he said.

Not surprisingly, this kind of analysis was unwelcome to those toiling within Lehman's mortgage banking and trading division. Gelband just didn't get it, they argued; he was too conservative. And Fuld tended to agree with them. Why did Gelband want to kill the proverbial goose that was laying golden eggs at a very rapid rate? The buzz, McDonald said later, "was that Mike Gelband had developed some kind of an attitude problem, and it needed to be changed real fast."[3] As Gelband's anxiety grew about Lehman's

exposure to what he saw as a catastrophe in the making, so did the worry among Lehman's top brass about Gelband and his inability to be a cheerleader for the business that was generating big profits for the firm.

In 2006, the volume and value of CDO deals hit another record, $552 billion—generating about $5 billion in profits for the Wall Street firms packaging the securities. But Gelband's anxiety grew just as significantly. That spring, some four million homes were for sale across the United States, double the number at the same time of year in 2000; CDO issuance was now more than three times the level of 2003. Gelband tried on several occasions to communicate those worries to Fuld and his chief lieutenant, Joe Gregory. At a year-end review in late 2006, Fuld openly told Gelband he was being too conservative. Ultimately, the naysayer had to go: by March, Gelband had been forced out of Lehman Brothers.[4] Only weeks after his departure, however, Gelband's predictions began to come true. Fuld may have won the battle, but Lehman would lose the war.

In the life cycle of every bubble, there is a point where it becomes clear that what looked like a boom is really a bubble—one, moreover, doomed to explode violently in the near future. By the early summer of 2007, that point had been reached. True, regulators such as Fed chairman Ben Bernanke could burble reassuringly about the problems associated with the subprime mortgage crisis being "contained," while Wall Street investment bankers remained publicly upbeat. But if the summer of 2007 was a tipping point, it is by studying the eighteen months that led up to it that we can begin to appreciate the extent to which Wall Street was afflicted with a kind of willful blindness or magical thinking. Each of the Street's five large investment banks, together with the investment banking divisions of giant global banks such as Citigroup and UBS, was fixated on doing whatever it took to maximize short-term profits. If one risky deal was highly profitable and thus good, then doing ten such deals had to be even better, they reasoned. With their gaze focused on their own bottom line, they neglected to consider the implications for the entire financial

system of each step they took. “We talked ourselves into complacency,” Blankfein later admitted during his FCIC testimony.

By the time Gelband began to warn his colleagues at Lehman Brothers about the impending storm, it was already on its way. At first it looked like nothing more than a single, distant cloud marring an otherwise perfect sky, or a small snowball rolling down an Alpine slope. But as the months passed throughout 2006 and early 2007, the number of clouds grew in number and became darker and more ominous; the snowball became a giant boulder and, moving faster and faster, threatened to trigger an avalanche that would crush everything in its path. At the time, few seemed to realize just what was brewing, yet the signs were everywhere. Nine of the ten largest leveraged buyouts proposed in the industry’s history were negotiated in 2006; subprime lending reached a peak along with CDO creation and leverage levels. Wall Street was drunk on cheap money and oblivious to the inevitable hangover.

The period that elapsed between two IPOs that, in different ways, signaled just how greatly Wall Street had changed over the last few decades proved to be the period in which that avalanche became unstoppable. The first of those transactions was the decision in the final days of 2005 by the New York Stock Exchange to merge with electronic trading network Archipelago and become, in the process, a publicly traded, for-profit entity. The second was the June 2007 initial public offering of stock in the Blackstone Group. The private equity group hoped to leverage its own decades-old brand name and its status as one of the linchpins of the “new” Wall Street into another successful nontraditional IPO. By now, however, the cracks in that new financial system were beginning to show up, and only days after the Blackstone IPO was completed, the financial apocalypse had begun. The fifteen months that followed would prove to be just as ugly and traumatic as the fifteen months that lay between the two IPOs had been filled with euphoria. Wall Street would never be the same again, the pundits proclaimed.

The Big Board Goes Public

In the final weeks of 2005, the New York Stock Exchange's 1,366 members prepared to vote on the most dramatic change to the centuries-old institution they ever expected to witness. Enough yes votes, and the Big Board would end 215 years as a member-owned nonprofit utility. Merging with electronic trading firm Archipelago Holdings Inc., the exchange would become a publicly traded for-profit entity whose activities revolved not around the venerable trading floor but around increasingly sophisticated computer networks.

To the exchange's new leadership—Goldman Sachs banker John Thain had just replaced Big Board veteran Dick Grasso at the helm in the wake of a scandal surrounding Grasso's lavish compensation package—the deal was a slam dunk. The exchange may still have been a symbol of American capitalism and the financial markets themselves, visited by every head of state that flew into New York to attend United Nations events. But, they argued, it was stuck in the twentieth century at a time when all of its major competitors at home and abroad had thrown themselves into the world of electronic trading. Its best clients—hedge funds and the trading desks of buy-side and sell-side firms alike—demanded execution in milliseconds, not seconds, especially for the vast majority of trades that simply involved buying or selling blocks of stock. The NYSE had taken a relatively slow and haphazard approach to computerized trading, and its ability to execute client trades cheaply and rapidly was in question even as the SEC forged ahead with plans to level the playing field still further. Supporters of the Archipelago merger argued that the deal wouldn't just make members rich—they would get, collectively, $400 million in cash and 70 percent of the shares in the new company—but also would save the centuries-old institution from becoming about as irrelevant as, say, a quill pen in the computer era.

Few Wall Street culture clashes are as visible as the one between the old and new Wall Streets that surfaced in the months after the transaction was sprung upon the world in the spring of 2005. The proposed merger had been negotiated in a matter of weeks, after

Archipelago was rebuffed in its attempt to acquire the Big Board's largest competitor, Nasdaq. Not a word of the negotiations—in which both sides were advised by Goldman Sachs—leaked out. On the day of the announcement, Archipelago executives attending the press conference snuck in a side door of the NYSE and up a back staircase to reach the room where the media was assembled in order to keep the news secret until the last possible second. "Rarely do you get to completely shock the Wall Street world, and we did," recalls one of the participants in the negotiations, gleefully.

Shock was the appropriate word. One NYSE member loyal to ousted exchange CEO Dick Grasso and angry about Goldman Sachs's increasing clout at the exchange (Goldman also owned a stake in Archipelago) tried to launch a rival offer. He argued that the deal didn't compensate seat holders for the value of the exchange's real estate at the corner of Wall and Broad Streets, much less its brand. On the floor of the exchange itself, a coterie of traders quietly mourned what they believed was the end of a long tradition. "I had always taken great comfort in the idea that the Big Board was above the fray, a kind of disinterested, nonprofit thing where our focus [as an institution] was to keep the wheels turning rather than only making money," one trader mused. "Obviously, we all wanted to make money for ourselves, but we also thought that the system within which we were making money was one that thought first about that system and only then about profiting for itself. I suppose we felt as if we had a kind of trust to discharge."

But the future lay with a new breed of player, such as Tom Caldwell, a Toronto financier who thirty-five years earlier had stood beside George Washington's statue outside Federal Hall, just across Wall Street from the exchange, and vowed to himself that one day he would own a seat on (and thus a stake in) the NYSE. By the time of the vote, Caldwell, now head of a multibillion-dollar investment empire, owned forty-nine seats on the NYSE and cast his own ballots in favor of the merger and the IPO. "When an exchange is public, when people are willing to own it, it's a sign of a stable financial system," argues Caldwell, who also owns shares of publicly traded stock exchanges worldwide, from Europe to Latin

America. “By having a publicly traded exchange, you give investors a way to participate in the growth of the economy and the region, and you give the exchange a currency that it can use to invest in itself to make sure it remains a competitive force.” The kind of push that comes from shareholder-investors to become more competitive and efficient is the best way to make sure an organization is as effective as possible, he adds. The NYSE just couldn’t afford to cling to its nonprofit status in a new world of intensive competition among stock exchanges for market share. It was this “new” Wall Street, with its emphasis on technology, innovation, and maximizing fees and revenues, that triumphed in the December vote. At least 85 percent of the exchange’s members (95 percent of those who cast their ballots) voted in favor of the transaction, Caldwell among them.

Three months later, shares of the new New York Stock Exchange Group began trading on its own exchange. Tiny ceremonial bells were handed out to all who showed up for the traditional party accompanying the first day of trading in any new listed company, and as the moment approached when exchange officials would ring the opening bell, members-turned-shareholders and hundreds of assembled guests began ringing them in celebration. The celebration was even louder at the end of the first day of trading, after the exchange’s shares rose from $67 to $80 apiece.

Nonetheless, everyone was well aware that this was an entirely different kind of IPO. For two centuries, the exchange had been a member-owned organization that wasn’t just a part of the financial system but one of its hubs. Even its location, at the corner of Broad and Wall, had given its name to that financial system—Wall Street. The reason for its existence was to give everyone a chance to access the secondary market for stocks. Unanswerable questions were everywhere. Some wondered what effect the fact that the exchange’s single largest holder was now a private equity firm—General Atlantic LLC—would have on governance.

It was early days for the merger, but even as the bells rang out joyfully, a chorus of boos was also heard on the trading floor. Some came from disgruntled floor traders who hadn’t had seats to sell and

who thus hadn't been made rich in the transaction, but who knew that significant upheaval lay ahead. Others, on and off the exchange floor, were wary for different reasons, and continued to voice their unease at the idea of a for-profit exchange. "Look, I think it's great that the NYSE is competitive and innovative, but I don't know how much thought has gone into finding a way to be both a utility that has to serve all of us who are market participants and a for-profit company that has to maximize shareholder returns," says one investment manager who has served on exchange committees in the past. "They had struggled with these conflicts even before they were public, earning profits for the exchange by selling the right to trade in certain stocks [specialist listings], even though they acknowledged those listings belonged to everybody who participated in the markets, not the exchange itself. I don't know how they'll cope with this over the long haul."

Cultural clashes such as these likely will recur for many years to come. Exchange insiders, on the other hand, point out that a separate regulatory company reports to an independent board of directors, while the exchange as a whole is still overseen by the SEC. And the risk is worth running, they argue. "If the exchange was a public utility, which implies being a kind of monopoly, then there would be no incentive for it to become better, faster, or more efficient; the competitiveness of our markets would suffer," says one former senior executive at the exchange. In other words, the profit motive was necessary; without it the exchange couldn't discharge its responsibilities to the system properly. Certainly, without the public listing the NYSE never could have taken its next step. Only a few months later, it signed a deal to merge with Paris-based Euronext, forming the first transatlantic stock exchange company and setting the NYSE on course to having a global footprint. The only way the NYSE could outbid Deutsche Boerse, its rival to acquire Euronext, was its ability to use its stock as the "currency" in the €8 billion offer.

Blackstone Cashes In

Little more than a year after the NYSE's debut as a public company, in June 2007, armies of television cameras showed up again at the New York Stock Exchange for another unusual kind of IPO. This time the company going public wasn't an exchange but an entity from another part of the Wall Street labyrinth: private equity giant Blackstone. Only a month before the IPO plan was announced, Blackstone's CEO, Stephen Schwarzman, had called the public markets overrated and not really worth it when it came to raising capital.[5] Now, it seemed, Schwarzman was willing to eat his words (which had been directed at hedge fund firms and rival private equity companies that had filed for IPOs) if it meant that he could raise nearly $700 million by selling part of his interest in the company he cofounded to other investors, and put a $7.7 billion valuation on the rest of it. It would quantify the magnitude of his achievement in the eyes of everyone—and make him even wealthier to boot.

On the surface, the deal looked appealing; it was pitched to potential investors as a way for them to get a piece of the private equity action that was usually confined to the deal makers themselves, their closest (very wealthy) allies in the finance and business worlds, and blue-chip institutional investors. The only problem was that owning Blackstone's stock wouldn't give ordinary investors access to the same riches they might have enjoyed as real partners in the private equity firm's deals. What Blackstone was offering to the public were shares in its management company, not participation in its deals. Moreover, investors would have limited voting rights, giving them little to no say over the way Schwarzman and his board decided to run the business. In the eyes of some potential investors, the Blackstone folks were hanging on to their cake even as they ate it.

The success of the NYSE's debut as a public company hinged on the ability of a centuries-old brand name to overcome worries that the newly merged company might not be able to reinvent its business model and compete successfully in the twenty-first-century era of computerized trading. Blackstone now faced its own set of

obstacles. Despite its status as a different kind of icon—a symbol of the riches that came from being a success on the "new" Wall Street—Blackstone's IPO bid raised eyebrows. After all, the firm had made that money for its partners and investors in its funds from private equity. Indeed, Blackstone's entire business model relied on the premise that the public markets it now sought to tap for its own benefit were inefficient. Only by taking publicly traded companies private (using debt to finance the deals) and overhauling and streamlining them could the true value of a corporation be unlocked, private equity investors argued. Of course, the public markets would come in handy eventually, when Blackstone needed an exit strategy to turn its investors' paper profits into cold hard cash. But an IPO wouldn't take place until Blackstone's partners had extracted as much value as possible from the company, leaving little on the table for subsequent investors. In other words, for Blackstone, the stock market had served traditionally as a dumping ground for its leftovers.

Nonetheless, Citigroup's Michael Klein, co-head of investment banking, felt the time had come for Blackstone itself to go public; the fascination with private equity as a source of fees for Wall Street had reached its logical extreme. It was time to turn those private equity profits into cash for the buyout firm's owners—and into fees for Citigroup. Klein, one of a small handful of bankers who pioneered the concept of sponsor groups within the investment banking world, had helped Blackstone finance so many of the firm's buyouts that Citigroup became known as Blackstone's bankers in much the same way that midtown Manhattan's Four Seasons restaurant, around the corner from the private equity shop's offices, was referred to as the Blackstone cafeteria. Klein broached the idea of an IPO for Blackstone itself not in Manhattan but over lunch at Schwarzman's recently acquired $34 million estate in the tony Hamptons.[6]

It was obvious that Blackstone had a better track record than many conventional companies that seek to raise new capital through an IPO. In the nearly twenty years that had passed since it launched its first fund, Blackstone's assets under management had

grown at an average rate of 34 percent. Even after paying Blackstone's fees, clients of its core private equity funds had pocketed an average annual return of 22.8 percent, a figure that dwarfed stock market returns in the same period.[7] Klein argued that Blackstone's managing partners could hang on to what mattered to them—control over the management of the funds and the ability to continue raising new ones—while generating a permanent capital base for the parent company and—not coincidentally—turning some of the wealth that Schwarzman, Peterson, and other partners had generated into cold hard cash. "It was very astute," says junk bond analyst and money manager Marty Fridson. "They seemed to realize that the market would never be at these levels again; a smart investor knows that the time to sell is when the market is at the peak and about to head south again. It was as if they'd said, 'Well, if people are willing to give us capital very cheaply, if they are willing to pay a premium—why not?' "

A Study in Contrasts

Aside from the timing and the nature of the deals—two parts of the Wall Street system for raising capital, raising capital for themselves through that system—the two IPOs could not have been a greater study in contrasts. The NYSE remains in many key ways a symbol of "old" Wall Street, despite the fact that 95 percent of the trading now takes place via computers rather than on the venerable trading floor. In contrast, Blackstone is the epitome of the "new" Wall Street. Even the purpose of the two IPOs was different. While that of the NYSE was simply a way to get the stock publicly traded (no fresh capital was raised), the Blackstone IPO was a way to help cofounder Pete Peterson (the former Lehman banker) make his wealth liquid: when the IPO was over, Peterson had sold all but 4 percent of his stake in Blackstone in exchange for $1.88 billion. Steve Schwarzman kept a 24 percent stake in the firm but still made nearly $700 million from the IPO.

Peterson and Schwarzman both rejoiced in lavish displays of their

wealth, with Schwarzman sometimes taking it to extremes. For his sixtieth birthday, celebrated on Valentine's Day 2007, Schwarzman commandeered the Park Avenue Armory; comedian Martin Short was the evening's master of ceremonies, Patti LaBelle sang a song written especially for the master of the universe, and Rod Stewart performed in an evening that—lobster, filet mignon, and all—cost $5 million, by some estimates. That was just slightly more lavish than Schwarzman's annual holiday parties, the 2007 version of which had an orchestra playing themes from James Bond films while models dressed as the various "Bond girls" mingled with hundreds of guests. He's also a property junkie, owning lavish homes in Manhattan, Jamaica, Florida, and Saint-Tropez, in addition to the Hamptons estate.

In contrast, Duncan Niederauer, the former Goldman Sachs banker who replaced John Thain at the helm of the stock exchange, plays down his own wealth in a more "old" Wall Street way even as he continues to urge the Big Board forward into a new era. He and his family live in a relatively modest New Jersey suburb and, until the exchange's security people put their feet down and insisted he agree to a car and driver, preferred to drive himself to work early every morning in a pickup truck. Schwarzman attends galas for high-social-impact institutions such as the New York Public Library; Niederauer prefers to work for Habitat for Humanity and an array of autism nonprofits. (His son was diagnosed as autistic as a toddler.) Still, Blackstone's IPO was "new" Wall Street, and the high-octane private equity business had, in the eyes of investors, a lot more pizzazz than the stodgy business of facilitating trades. While the exchange's stock had dipped below its $31 IPO price by the summer of 2007, Blackstone and its underwriters were confident that all that glamour would command a premium valuation.

Certainly the buyout business seemed white-hot, with several veterans speculating openly that 2007 or 2008 would see what many bankers and analysts had believed to be impossible: a $100 billion buyout. "That November 2006, we were working on three or four deals all at once, and then we got a call to work on

structuring what would have been an $85 billion buyout," says one Citigroup banker. (By way of comparison, the largest buyout to date had been the $33 billion purchase of hospital chain HCA in the summer of 2006.) The bankers figured out ways to sell no less than $35 billion of term loans and worked through different strategies for financing the rest of the transaction but—to the poorly hidden relief of at least some of the bankers—the transaction fell apart. "Someone made the comment, 'I think we just flew too close to the sun.' "

Even for those who believed in the fundamental strength of the private equity model, the rapid-fire pace at which new buyouts were being done, the enormous deal sizes (seventeen of the twenty largest deals in history were announced in the eighteen months that preceded Blackstone's IPO), and the equally gargantuan valuations and levels of debt aroused unease. "Why would I want to buy stock in Blackstone if a guy like Steve Schwarzman is selling?" was the question heard across Wall Street. Those qualms didn't stop the underwriters (led by Morgan Stanley and Citigroup) from rounding up more than enough interest to price Blackstone's shares at $31 apiece, at the high end of the range. Behind the scenes, the level of nervousness was growing, say people who were involved in the underwriting and the road show. "Steve decided to accelerate the pricing by two days," says one of the bankers. "He saw the environment deteriorating."

In Washington, Senator Charles Grassley (the ranking Republican member of the Senate Finance Committee) was "stomping around," in the words of one private equity deal maker, introducing, along with his Democratic counterpart and committee chairman Max Baucus, a proposal that would tax the 20 percent share of profits earned by partnerships such as private equity, venture capital, and hedge funds at the rate applied to corporate profits rather than at the much lower capital gains tax rate. Meanwhile, the leveraged loan market—on which Blackstone and other private equity funds relied to help finance their deals—was beginning to crack. "In 2005, a normal backlog of paper that banks had committed to finance and waiting to be sold would be about $70 billion, but by

June of 2007, it was $380 billion," says Tom McNamara, the private equity banker. "The tidal wave of paper in search of a home was so overwhelming that almost overnight we started to hear investors starting to say no to deals and commenting that they didn't need to buy everything, especially at the prices being asked." Schwarzman's instincts were right. Within days of the Blackstone IPO, shares of the newly public company (trading under the symbol BX—pronounced "bucks," as in cash) were falling; by early July 2010, the stock was changing hands for $16.50 a share, about half its IPO price of $31, although three times its 2009 low.

Flying Too Close to the Sun

Before the Blackstone IPO had been completed, the pendulum reached one extreme and began, slowly, to swing back in the other direction, gathering speed as it went and culminating in the Wall Street debacle of 2008. During the months that elapsed between the two IPOs, nearly everyone on the Street—from veteran regulators to the greenest traders—recalls experiencing some kind of eureka moment: a point in time where they stopped what they were doing and reflected to themselves that the good times they were experiencing were unsustainable. For some, the warning signal was a particular deal that made them realize just how much risk their institution and the rest of the market was accepting without question. For others, it was an offhand remark by a colleague, or being confronted with the kind of careful research presented by a handful of Wall Streeters such as Mike Gelband to their colleagues and bosses.

In the early spring of 2006, during the celebration of the stock exchange's IPO, the warning signs were subtle and articulated only by those willing to be provocative and challenge the status quo. Even months later, few were willing to listen to Gelband and others like him, those whom Wall Street CEOs such as Fuld were quick to label as false prophets of doom and professional worrywarts. After all, fee income and profits at investment banks and other firms hit

record levels in 2005, for the fifth year in a row; so, too, did compensation. Collectively, Wall Street firms pocketed $34.1 billion in bonuses in 2006. At the annual Robin Hood Foundation gala that December, the hedge fund managers who had founded the antipoverty charity took from the rich (themselves) and gave a record $48 million to the poor of New York City.

As the weeks passed and the clock ticked down to the Blackstone IPO in mid-2007, the warning signs became more pronounced. Crude oil prices had been rising, putting a crimp in the budgets of those who, unlike Schwarzman, didn't have billions in spare cash to cover the increased costs of heating even one home. But with twenty-twenty hindsight, one would have to say the real party pooper was the Federal Reserve, which had begun raising interest rates back in June 2004. Until then, policy makers had spent some three years flooding the American financial system with cheap capital in hopes of staving off a sustained period of recession and averting deflation in the wake of the stock market crash that had begun in 2000. That prolonged period of readily available, ultracheap debt fueled the boom in private equity deal making that made private equity firms such as Blackstone so superficially appealing, as well as generating other trading and underwriting fees for fixed-income bankers across Wall Street.

It also distorted the perception of the risk of many transactions. Why worry that many of the new asset-backed securities being repackaged by Wall Street involved so-called subprime credit card receivables and mortgages—debt owed by borrowers with tattered credit histories? Low interest rates would cover a multitude of sins, and in the meantime, there were rich fees to be harvested. Until there was evidence that Wall Street's hubris, in the shape of its quest for more and more profitable fee-generating business, had collided head-on with the forces of gravity, no one on Wall Street wanted to worry. "Why would we borrow trouble?" says one former senior Wall Street executive. "We had to keep making money, keep our shareholders happy."

The Quest for ROE

Keeping shareholders happy had been the name of the game on

Wall Street ever since the first big wave of investment bank IPOs culminated in the decision by Bear Stearns to go public in 1985 and Morgan Stanley to follow in 1986. By the early 2000s, a tidal wave of consolidation and the collapse of the regulatory barriers that had once separated investment banks and commercial banks had reshaped the competitive landscape dramatically. Just as the changes in the 1960s had pushed many firms out of the business, the trends of the 1990s caused bank and investment bank CEOs to question their ability to go it alone. Technology costs were soaring; paying key employees enough to stop them from jumping ship and heading off to work at hedge funds or buyout shops drove up expenses, as did maintaining a global footprint. Meanwhile, profits from traditional businesses, such as trading, were continually under pressure.

For many Wall Street institutions, the answer seemed to be joining forces with a giant global institution. The U.S. division of UBS, the Swiss powerhouse bank, acquired PaineWebber in 2000, ending the latter's 120 years of independence. (The PaineWebber brand name vanished three years later.) Credit Suisse, UBS's rival at home in Switzerland and overseas, had become an aggressive investment banking competitor to firms such as Goldman Sachs and Morgan Stanley in the late 1980s, when it snapped up First Boston and its powerhouse M&A division, which employed two of the biggest buyout bankers around, Bruce Wasserstein and Joseph Perella. (Wasserstein died suddenly in late 2009 at the helm of Lazard, while Perella now runs his own boutique, Perella Weinberg Partners.) It followed that up with the purchase in 2000 of Donaldson, Lufkin & Jenrette.

The big U.S. banks were just as interested in getting a share of Wall Street profits that, in good years, dwarfed the skimpy margins they could earn from commercial banking operations. Sanford "Sandy" Weill got the ball rolling by forming a new financial services behemoth, Citigroup, which would bring together a major bank (Citibank) and an insurance company (Travelers Group). Back in 1997, Wall Street's Salomon Brothers ended nearly eighty years of effective independence when it agreed to be acquired by

Travelers Group; when Weill created Citigroup, he brought together a commercial and a major investment bank for the first time since the Depression-era passage of the Glass-Steagall Act. Weill's 1998 deal forming the future Citigroup violated that law, but Weill was given a two-year waiver; sure enough, in 1999, an obliging Congress officially repealed the crucial parts of Glass-Steagall and opened the door to the creation of other financial conglomerates. J.P. Morgan became JPMorgan Chase; other players, including Bank of America, became viable competitors to the traditional stand-alone investment banks on Wall Street. One after another, small investment banks sold out or were acquired by their larger rivals, with Deutsche Bank picking up Alex. Brown. Chase had acquired Hambrecht & Quist before its own purchase by J.P. Morgan. NationsBank purchased Montgomery Securities and later merged with BankAmerica to become Bank of America.

Now traditional Wall Street firms such as Morgan Stanley, Bear Stearns, and Lehman Brothers found themselves jostling for deals and profits with new or suddenly stronger players in the investment banking arena, such as Citigroup, UBS, and J.P. Morgan, all of which had vast amounts of capital at their disposal. It didn't matter whether they had originally been commercial banks or investment banks; all were now engaged in a relentless battle to maximize their return on equity. "The higher the ROE, the higher the book value of the investment banking operations and therefore the higher the stock price can climb," explains Jeff Harte, an analyst at Sandler O'Neill who has been studying the investment banking universe for many years. "It tells you how hard the bank's managers have been making the capital work, and how good they are at doing their job."

A bank can boost its ROE by moving into higher-margin products or into business areas that don't require it to use a lot of its own capital (one reason so many institutions are eager to move into wealth management), or by using leverage, which is borrowed money. Between 1975 and 1984, securities underwriters reported an average after-tax ROE of about 16.2 percent. Commercial banks had a smaller return on equity because their equity base tended to

be much larger; in the same period the ROE of commercial banks averaged 12.3 percent.[8] By 2000, average ROEs had crept higher, even as traditional high-margin businesses came under pressure. Three years later, as both the financial markets and the investment banking industry began to recover from the dot-com blowup and the Enron and WorldCom governance scandals, a gap started showing up in the ROE data.

Goldman Sachs was pulling ahead of the pack decisively: in 2004, it generated an ROE of 19.8 percent while perennial rival Morgan Stanley earned 17.2 percent, Citigroup investors were rewarded with 17 percent, and Bank of America posted an ROE of 16.5 percent. Bringing up the rear was Merrill Lynch, with an ROE of 15.7 percent. Among the major Wall Street players, the only institution able to challenge or surpass Goldman in the ROE sweepstakes was Bear Stearns, which, thanks to its aggressive use of leverage and willingness to put its capital to work on its proprietary trading desk, earned an ROE of 19.1 percent.[9]

"The call went out around the Street—we had to beat Goldman's ROE," says one former top banker who worked for a rival firm. "Every quarter, there was a debate over how we could reduce equity and increase leverage to make the ROE look better, over ways to squeeze an extra penny or two out of each of the business units." The pressure on Wall Street's CEOs and CFOs made them look, once again, at the fate of Phil Purcell at Morgan Stanley. Overlooking Purcell's shortcomings, they focused on the fact that it was discontented shareholders who had spearheaded the coup d'état. Had Morgan Stanley posted a higher ROE in 2004 (when it trailed all but one of the four other top investment banks), they figured those investors wouldn't have been quite as eager to oust Purcell. "It was very, very apparent to every CEO on Wall Street that Phil Purcell had been run out of Morgan Stanley because he couldn't keep up with the ROE that Goldman had, because he wasn't using leverage enough and taking enough risks," the former banker adds.

The pressure on the rest of Wall Street to keep pace with Goldman Sachs continued to grow as Goldman's ROE increased and

the gap between its performance and that of its rivals widened. In 2005, Goldman reported an ROE of 21.9 percent, climbing to 33.3 percent in 2006 and again in 2007. At Bear Stearns, meanwhile, 2005's ROE actually fell, to a measly 16.5 percent, as did that at Morgan Stanley, which hit 15.9 percent. At Merrill, it rose to 15 percent and up another fraction to 15.7 percent in 2006; Citigroup saw ROE rise to 17.5 percent in 2005 and then 17.9 percent in 2006. Wall Street was motivated to catch up with Goldman, since a hefty ROE was usually followed by an equally large payday for employees. In 2007, for instance, when Goldman paid an average of $661,490 to each of its employees, those at Lehman Brothers earned about half that, or $332,470.[10]

Chasing Goldman Sachs was a risky proposition. "Goldman was posting those kinds of returns because of decisions it had made years ago. When, after the downturn in 2000, all the other investment banks really cut back their exposure to risk and walked away from their risky business lines, Goldman Sachs didn't," Harte points out. In other words, they had been thinking strategically when their rivals hadn't been focusing on the long-term opportunities at all. They had learned to zig when others zagged.

Elsewhere on Wall Street, the perception was that Goldman had relied solely on risk taking—borrowing to finance proprietary trading and investments—and that firms that hadn't kept up had failed to do this as thoroughly or as adeptly as Goldman. That implied that the problem could be quickly reversed if Goldman's rivals just hired the right people, focused on the right products, and pursued the right strategies. Some of Goldman's rivals, like UBS, hired consultants to advise them on how to keep up with Goldman. At Citigroup, managers approached Bob Rubin—the Goldman Sachs alumni now playing a senior strategy role at the firm since becoming a director—with ideas for how to beat Goldman at its own game; aggressive as he was, Rubin firmly rejected many of the ideas, say people familiar with the events; Citigroup simply had neither the talent nor the risk management skills to make it worthwhile. "Part of the reason that didn't happen the way they expected was that they missed out on the fact that Goldman had

been investing in things like building up commodity trading in Asia long before 2003," when commodity markets ignited, Harte adds. When Goldman's ROE surged and investors in its rivals demanded that they do what it took to match those gains, taking two or three years to design and implement a long-term strategy wasn't an option. "The only way to accomplish what investors wanted as rapidly as they wanted was [by] taking on more leverage and getting more deeply into riskier businesses, or at least businesses that, if you were evaluating them properly, had more risk in them than might appear on the surface."

Chasing Market Share

By the spring of 2006, the battle for market share was at its most feverish. Across Wall Street, bankers deciding whether to undertake a new piece of business never asked themselves whether that transaction was good value for investors or even their clients over the long term. Nor did they seem to question whether the short-term rewards (the fees, higher profit margins, and higher ROE) made sense in light of the longer-term risks to the investment bank, its clients, or the financial system. The only question that mattered was whether the deal could be done and how much the institution could earn from it.

The risks associated with the securities the banks were packaging or underwriting were less important than the bank's ability to shift that risk off to someone else—specifically, to transfer it to an investor. Buyout banker Tom McNamara knew he would be viewed as less than a team player when he questioned his boss about a large private equity transaction that took place in the autumn of 2006. In the same way that subprime borrowers were buying homes with a 5 percent down payment rather than the traditional 20 percent, the buyout firm proposed to invest only a fraction of the equity typically committed to deals of this sort. McNamara's boss, he recalls, looked at him and asked, "What's your problem? Can't you sell the [junk bonds and leveraged loans]?" McNamara,

in a bid to explain his concerns, began to reply, "Yes, but—" only to have his boss cut him off. "That's all I need to know. If we don't do the deal, [our biggest rival] will. So do it." McNamara never again questioned a borderline deal, however risky it looked to him.

That pattern was the same across Wall Street. "How can a loan officer who is under pressure to produce loans realistically say, 'Maybe we should sell less loans?' and keep their job," said Mike Mayo in his FCIC testimony. Even Mayo, theoretically an independent analyst, experienced the backlash. When he wrote critically about compensation issues within the banking world in the late 1990s, some of the Wall Street institutions he was charged with monitoring began to block his access to the data he needed to do his job. "The reaction … was that these issues were none of my business." He began disclosing the lack of access to his clients and testified to Congress about the problem. "If I face a backlash even after I testify to Congress on backlashes," then why expect more from someone at the heart of the system? Mayo queried.

Certainly, none of the clients questioned the readiness to make a deal on the part of Wall Street. "We examined each deal in a vacuum," admits Jake Martin, the private equity firm executive. Looking back, he says, it's easy to understand why buyout fund managers such as himself and their bankers never moved beyond thinking how to do each individual deal long enough to consider the effect on the financial system of all that low-cost, high-risk borrowing. "It's a flaw of human nature." Martin says no one stopped to think about the cumulative effect of all this leveraged lending. Now, he acknowledges, it should have been obvious that those large and risky loans were going to make any downturn far worse than it otherwise would have been. "When everybody is doing exactly what you're doing, that is the time to stop and question what it is you are doing," he now says.

In 2006, the cumulative impact of all that frenzied deal making was showing up in the profit statements posted each quarter by Wall Street's investment banks. One after another, they announced big jumps in revenue, earnings—and, of course, ROE. Back in 1996, Morgan Stanley had earned $22.1 million in fees handling a dozen

mergers for private equity clients, and a total of $52.1 million from all of the investment banking mandates those funds had awarded to it. In 2006, the firm earned $271.7 million in M&A fees alone, and $520.7 million from sponsors in all kinds of investment banking fees. Not only were those private equity transactions growing in number, but the rate of growth in profitability (and thus contribution to the ROE) dwarfed that of conventional transactions. In 1996, advising on an investment banking transaction for a sponsor earned Morgan Stanley an average of $1.3 million; a decade later, the average fee had soared to $3.35 million. No wonder McNamara's bosses didn't want to stop and question the deals they were working on, any more than a buyout manager wanted to discover that his bankers were suddenly insisting they would only finance his deals on more conservative terms. By comparison, the rate of growth in fees paid by clients for routine investment banking transactions was far more modest: the average transaction earned the bank only $1.9 million, up from $1.35 million in 1996.[11]

The bankers who spent their time frantically cobbling together leveraged loan packages for their buyout firm clients and CDOs stuffed with more and more questionable mortgage loans, coined a new phrase. When one voiced a qualm, another would toss out the acronym "IBGYBG," or "I'll be gone; you'll be gone." In other words, by the time the chickens came home to roost—by the time the deal eventually soured and left investors demanding explanations—the bankers in question would have long since pocketed their bonuses and moved on. None of them, it seemed, spared even a thought for the institutions for which they had worked and that would be left behind, much less for the financial system.

The Thundering Herd Runs Amok

The hunt for ROE would prove to be particularly dramatic at Merrill Lynch, the ninety-two-year-old investment bank best known

for the strength of its vast retail brokerage network, dubbed the "thundering herd." While Morgan Stanley and Goldman Sachs had earned their investment banking chops by working with corporate clients to underwrite stock and bond issues and advise on mergers, Merrill traditionally demonstrated its clout by selling those issues via its horde of brokers. The problem was that simply acting as the middleman or gatekeeper in plain-vanilla transactions was no longer the best way to earn a respectable ROE. Merrill's board of directors had handed CEO Stanley O'Neal a clear mandate to make the firm competitive, by which they meant generating a higher ROE. At the end of 2005, Merrill's ROE was only 15.7 percent, compared to the average for the investment banks of 18.4 percent.[12]

That's when directors approved a new compensation policy: the more O'Neal and his chief lieutenants could boost the firm's ROE, the more generous their compensation packages would become. Now O'Neal had an explicit incentive to do what he wanted to do anyway—transform "Mother Merrill" into an elite Wall Street institution that could be spoken of in the same breath (without irony) as Goldman Sachs. O'Neal was convinced that the way to do this was to push Merrill into new business areas, away from its traditional reliance on the now stodgy business of underwriting and selling stocks and bonds. He told everyone on Wall Street that he intended to take Merrill in the direction of becoming a principal player in the world of trading and as an investor. In 2006 he demonstrated just how to do so and hit the ROE targets set for him.

Even as the compensation committee was drawing up its new rules the previous year, he and his senior executives had begun to take the first steps to deliver what investors and directors wanted. They started by carving out a role for Merrill in what would become (as of that date) the second-largest leveraged buyout in history, the $15 billion purchase of car rental chain Hertz from Ford in December 2005. It collected fees for advising buyout firms Clayton, Dubilier & Rice and the Carlyle Group on the deal, and pocketed more fees for underwriting the billions of dollars of loans and bonds needed to finance the transaction. But Merrill Lynch also

became an investor alongside the two private equity firms, which collectively invested only $2.3 billion of their own money in the transaction, using the debt that Merrill raised to pay for the rest. Within ten months, Merrill had recouped $400 million of its $748 million share of that equity stake, thanks to a series of "special dividends" that Hertz paid its new owners. One of those special dividends was paid out of the proceeds of Hertz's IPO in November 2006, which also generated (not coincidentally) more underwriting fees for Merrill. By the end of 2006, one analyst calculated that the firm had already doubled its money on the Hertz investment—even without taking into consideration the value of all those fees. Merrill beat out every investment bank except Goldman Sachs for the title of most profitable firm on the Street that year, and generated more profits than it had in its history.

Merrill began investing more aggressively alongside private equity firms in other buyouts. When its bankers visited executives at HCA, America's largest for-profit hospital chain, in early 2006, they arrived with a decidedly different kind of pitch, one that HCA wasn't accustomed to hearing from bankers. Instead of suggesting that HCA buy some more assets or even bid for a rival, Merrill proposed that it would put together a "club" of buyout funds—itself chief among them—to take HCA private in a leveraged buyout. After recovering from their astonishment, the HCA honchos agreed to be acquired by a group that brought Merrill together with Bain Capital and KKR. The $31.8 billion deal would finally eclipse the KKR-financed acquisition of RJR Nabisco in 1989 and become the largest-ever such transaction. That's what grabbed the headlines; left unanswered was the question of just how the buyout investors would add value.

"This deal was a real red flag," recalls Marty Fridson, who analyzed the junk bonds being sold to finance the transaction. "What was the plan for improving HCA? Nothing." There were whispers of a secret plan to sell a bunch of hospitals and restructure the company, but nothing was announced or materialized, he says. "Really, they were just buying a company that was selling at a fifty-two-week low and using borrowed money. Basically, they were

saying to their own investors, 'There aren't any more beaten-up or battered companies that need us to help fix them.... So we're going to buy stocks in the public market with borrowed money and, knowing that stocks go up over time, count on that to help us earn a good return.' " Fridson points out that investors could have done the same thing for themselves by purchasing HCA stock on margin —and they wouldn't have had to pay a 2 percent fee or 20 percent of the profits to the buyout funds. "But that wouldn't have had the allure of being invested in a top buyout firm," Fridson adds with a dash of cynicism. Sure enough, one of the partners—KKR—had marked down the value of its stake in HCA by a third by early 2009, according to a regulatory filing.

Still, in the short run, O'Neal's team was finding other ways to make all these new fees and other earnings from deals such as the HCA buyout generate a bigger bang on the bottom line that had more to do with accounting than investment banking. One logical strategy to boost ROE and make it look more impressive was to reduce the amount of equity on the investment bank's balance sheet; the smaller the number of shares over which those earnings must be divided, the higher the ROE. So the firm spent $9 billion to buy back stock and borrowed to add assets to its balance sheet. Instead of selling its own stock at the top of the market—Blackstone's strategy—Merrill was buying it back.

Rivals and risk managers understood why O'Neal and the board had signed off on the plan. Still, some questioned the wisdom of the strategy, despite the record-breaking earnings Merrill posted quarter after quarter in 2006. "They were counting on the good times keeping going, and that their ability to unwind the risky, high-leverage deals they were doing would always be there," says one hedge fund manager who says he decided to sell Merrill Lynch stock short, betting that its price would decline, after hearing of the stock buyback plan. "Okay, so they maximized their ROE in the short term, but then they took away the capital cushion they might have used to cover any losses when things went wrong." Anyone with any sense, he adds, knew that a reckoning was just a matter of time.

But within Merrill's executive suite, no one seemed to be looking further ahead than the next three-month earnings announcement, at least when it came to risk. As well as the profits and fees associated with the investment in Hertz and other transactions in which it was a principal rather than an intermediary, Merrill had made $7 billion using its own capital to make trading bets, up from $2.2 billion in 2002. In January 2007, a triumphant O'Neal reported "the most successful year in [Merrill Lynch's] history": the investment bank had earned a record $7.5 billion and its ROE hit 20.7 percent, beating Citigroup, Bear Stearns, and even Morgan Stanley. If the company needed its own fleet of Brink's trucks to haul away its gains for the year, so would O'Neal. Although his salary for the year was a relatively paltry $700,000, his total compensation package soared to $48 million. Few within the firm seemed to be concerned that by the time the Blackstone IPO was priced, Merrill was sitting on a record $1 trillion in assets, more than double the level of four years earlier.

Working more closely with private equity firms wasn't the only high-risk business that Merrill Lynch had pursued as part of its quest for a higher ROE. Another source of hefty profits in 2006 and into the first half of 2007 came from a corner of the banking world that was still further away from Merrill's traditional area of expertise and Wall Street's core functions. Merrill had joined what was becoming known as the shadow banking system, moving beyond assisting buyout managers to saddle their portfolio companies with artificially cheap debt loads to help America's homeowners saddle themselves with artificially cheap debt in the shape of mortgages and home equity lines of credit. Drawing on new technology as well as their sales network—they could resell their structured products to clients in the same way that they marketed stocks and bonds—Merrill could earn outsized fees for packaging and repackaging home mortgages and other income-generating assets for resale to yield-hungry investors. It had started small—securitizations amounted to only $350 billion or so in 1981—but by 2001, Wall Street underwrote $3.3 trillion of newly securitized bonds.

The market for residential real estate had hit $18.4 trillion by the end of 2004, and the mere idea of finding a way to link such a gargantuan market with the ultraliquid debt markets was alluring. Making it possible was the fact that investors were fed up with the low returns that accompany low interest rates and were clamoring for bondlike investments that generated higher yields in much the same way that investment bank shareholders were clamoring for higher earnings and an ROE to match that of Goldman Sachs. Maybe a push into structured finance could keep both groups happy?

The Mortgage Machine

In the summer of 2006, as one team of Merrill bankers and investors prepared the way for Hertz's IPO in a few months' time, another group was negotiating the $1.3 billion purchase of First Franklin, a San Jose, California–based mortgage origination "machine" that had underwritten some $29 billion of home loans the previous year. The motivated seller was National City Corp., a bank based in Cleveland, Ohio; perhaps its executives, like those of Blackstone, were relieved to be getting out of at least part of the mortgage business at what already seemed to be the peak of the market. For its part, Merrill Lynch was an equally motivated buyer. Its mortgage bankers were relieved to have another way of feeding its securitization habit, one the firm had acquired early on in Stan O'Neal's tenure as part of his push to boost risk-taking businesses and ROE.

Securitization was one of the first-generation innovations on Wall Street in the post-Mayday environment, pioneered by Lew Ranieri and his colleagues at Salomon Brothers. "Like all innovations, it started out as a great idea and ended up in craziness, with loans structured in ways that only a few Ph.D.'s can understand, and where there's no obvious purpose for its existence," says Rob Kapito of BlackRock.

Kapito was one of the next-generation innovators in the securitization market during his years at First Boston (later absorbed

by Credit Suisse), where he worked for BlackRock's founder, Larry Fink, to develop what was then referred to as the collateralized mortgage obligation (CMO) market in the early 1980s. He watched the market explode in both size and complexity. The CMO was another way to put together a pool of mortgages and make them appealing investments by splitting them into tranches, or slices. The topmost tranche—the senior layer—would pay less in interest but would be of lower risk or higher quality, or perhaps be shorter term in length; in one alternative structure, one tranche would consist of bonds that sold at a discount and paid no interest (zero-coupon bonds), while the other would be an interest-only tranche that would fluctuate in value along with interest rates (as investors prepaid their mortgages, the flow of interest income would taper off). "The whole idea was to give investors a security that met their specific needs—low risk, or high yield, or shorter duration," notes Kapito. By the late 1980s, he adds, the CMO market was starting to run amok. "All of a sudden there were structures out there that didn't make sense, Ph.D.'s making bonds look better than they really were—and they blew up. And we all said, 'Okay, let's get back to something simpler.' "

In the era of rock-bottom interest rates that began in the fall of 2001, when the Fed started slashing interest rates, and reached its peak in June 2003, when key lending rates fell to 1 percent, it made sense for both sides of the market—and for bankers—to take another look at the way home mortgages were securitized; at this point, new mortgage origination had hit a record of $3.9 trillion. Many homeowners wanted to refinance their properties, while new buyers were being lured into the real estate market by the combination of ultracheap financing and ample liquidity, thanks to the de facto national financing market that securitization had created during the 1980s. Not surprisingly, issuance of mortgage-backed securities soared. They also became more complex, and thus more profitable for the Wall Street firms who were buying these mortgages from savings and loan institutions as well as the growing array of nonbank institutions that had set up shop explicitly to make these loans.

In 2000, mortgage-backed-security-related transactions generated only $690.7 million in fees; by 2006, that had climbed to $2.3 billion. And the average transaction generated $1.8 million in fees in 2006, up from $1.3 million six years previously.[13] It didn't hurt, either, that a bank that could funnel its mortgage loans into some kind of structured product—especially a highly rated CDO—could reduce the amount of capital it had to set aside to guard against writedowns. Even trading in these securities was becoming a money spinner. All that home-buying activity sent housing prices soaring: the median house price jumped 27.6 percent in the three-year period between 2001 and 2004, when Federal Reserve policy makers decided to begin pulling away the punch bowl full of cheap money. In contrast, for more than a century, housing prices had risen less than 1 percent a year. That rise in valuation triggered still more activity for mortgage originators and parts of the shadow banking system, as borrowers refinanced their mortgages or took out lines of credit secured by the equity that had suddenly appeared.

Merrill Lynch wanted a piece of that business, and O'Neal hired Christopher Ricciardi from Credit Suisse to get it for them. Ricciardi was an expert in collateralized debt obligations, around which the latest incarnation of the mortgage finance market was built. In the latest twist on the CMOs that Kapito and Fink had structured at First Boston in the 1980s, CDOs were divided up by risk level, with higher-risk pieces carrying a higher yield; some tranches won a triple-A credit rating from Moody's and Standard & Poor's, and offered a small but still appealing premium over other top-grade securities. Part of Ricciardi's job was to make sure he could get the mortgages he needed in order to structure the mortgage-backed bonds and then the CDOs.

Under Ricciardi, whose efforts ultimately propelled Merrill into first place in the CDO league tables, Merrill Lynch was a particularly aggressive bidder for the mortgages that mortgage originators were churning out at an increasingly rapid rate to meet the insatiable Wall Street demand. By 2004, those mortgage originators were convinced that Merrill was buying market share—

in other words, it was paying more than its rivals believed the mortgages were worth just in order to obtain the loans to stuff into their CDO creation machine. By the end of 2005, CDO issuance had nearly doubled from 2004 levels, hitting $271.8 billion.[14]

But 2006 and the first few months of 2007 would mark the peak of this bull market and deliver some of the first major warning signs of the apocalypse that was taking shape here just as in the private equity arena. At least it did for those who, like Lehman's Gelband, were looking for any signs that the boom was really a bubble in disguise. Fitch Ratings, a credit rating agency, slapped an alert on one subprime lender as early as the final months of 2003. By early 2004 the Federal Reserve system (which regulates banks) began picking up signs that the quality of the loans being made by banks, nonbank mortgage originators, and others was deteriorating. That year CDO issuance would peak at $520.6 billion and subprime lending would also reach new highs, five times the level of five years earlier. Lenders were scrambling to feed the Wall Street mortgage machine, even if that meant lending money to people who could present no evidence that they earned enough to keep up payments on the loan or whose credit ratings were wobbly. They developed new structures to enable them to rationalize signing off on these risky mortgages, including "no-doc" loans (also known as liar loans), which didn't require any proof of income, and interest-only loans. Among the most toxic were mortgages with ultralow teaser rates that would reset later at much higher levels that the unwary borrowers often could not afford.

The aggressive marketing of mortgages to fuel the CDO creation machine tipped over into fraud, a number of former salespeople have admitted. Within a month of the day he started working as the head of the mortgage fraud investigations division at Ameriquest, one of the biggest subprime players, Ed Parker later told the Financial Crisis Inquiry Commission that he had spotted signs of fraud in the loans being made. The response? Those whose bonuses depended on the machine working smoothly and at maximum velocity complained that Parker "looked too much" into the loans. By November 2005, he had been demoted, and then—evidently

having failed to take the hint—Parker was laid off in May 2006. The reason for the fraud initially surprised Parker and his peers, until they were told to "look upstream." In other words, they needed to recognize the hunger on Wall Street for more and more mortgages that could be bundled up and resold to investors.

Wall Street itself was doing whatever it could to keep the mortgage machine chugging along. In October 2005, Merrill Lynch had purchased a 20 percent stake in Ownit Mortgage Solutions, one of the growing coterie of nonbank mortgage originators, to keep the mortgages flowing onto its books. Within a few months, Ricciardi had left to launch a specialized CDO investment boutique of his own; he wasn't around to see the value of the mortgage-related assets on Merrill's books spike to a high of $52 billion from a mere $1 billion back in 2002.

The CDOs being structured with those mortgages carried increasingly exotic names that gave no hint of the risky nature of the underlying assets; some hinted at prosperity (Golden Key) or the good life (Costa Bella). All generated lavish fees for the Wall Street firms. Every time another $500 million or so of mortgages were repackaged first into mortgage-backed bonds and then into CDOs, the underwriters picked up $5 million in fees. BlackRock portfolio manager Scott Amero could boycott the deals when he realized what was happening, but that was it. "Look, I couldn't stop the market; I couldn't stop Wall Street from doing what it was doing," Amero says now. "All I could do was stop participating in this Wall Street–style food fight as everyone demanded higher yields."

By the fall of 2006, even Ranieri, the godfather of the mortgage-backed securities market, had sent out an edict banning anyone who worked for him from touching the increasingly poor-quality CDOs.[15] By then, Merrill was negotiating the acquisition of First Franklin, described by the firm in a press release as "one of the nation's leading originators of non-prime residential mortgages" (aka a big subprime lender). Dow Kim, president of Merrill's investment bank, who had taken over the business on Ricciardi's departure and publicly pledged to the team of mortgage bankers that he would keep the good times—and deal flow—rolling.

proclaimed his view that owning First Franklin would enhance "our ability to drive growth and returns" higher.

It should have already become clear that subprime lending, whatever it had done for the ROE of Merrill Lynch and other investment banks in earlier days, was more likely to be a source of losses than profits in the years to come. Merrill announced the First Franklin transaction in early September; by December, when they forked over the purchase price and celebrated the closing, the investment bank was in the midst of a spat with its 20-percent-owned mortgage provider, Ownit. Some of the loans that Ownit had fed to Kim's banking team were going sour within months of origination, just as Amero had discovered, and Merrill was pushing the firm to buy back the loans.[16] Ownit, balking, closed its doors in December, just as First Franklin became part of Merrill Lynch. While CDO issuance would keep climbing until the late spring of 2007—about the same time that Blackstone completed its IPO—and would peak at $178.6 billion in that three-month period, it was becoming increasingly clear that hyperaggressive risk taking on Wall Street was no longer a recipe for quick and outsized profits.

The love affair between Wall Street and extreme banking had been intense, exciting, and highly lucrative during the fifteen months that separated the IPO of the New York Stock Exchange and that of Blackstone the following summer. Everyone had been eager to keep the music playing and to continue dancing. But in their mania to generate ever higher returns on equity, Wall Street institutions had succeeded in distorting the financial grid beyond all recognition as they pursued one fee-generating opportunity after another. There was no possible reason for any banker to create a CDO-cubed, as bankers acknowledged in the calm that followed the Wall Street storm of 2008. "But we did it anyway," one former Citigroup banker admits somewhat sheepishly.

The irony was that Merrill Lynch's frenetic dealmaking in pursuit of higher returns on equity and a dominant market share in the CDO business ended up driving some of the final nails into the investment bank's coffin. In a move that was becoming all-too-typical, Merrill became its own best customer: As the FCIC

reported, 134 of the 142 CDOs Merrill built and sold between 2003 and 2007 contained at least one slice of another Merrill CDO; anyone digging into a Merrill Lynch CDO during this period was likely to find that at least 10 percent of the collateral was made up of securitized mortgages from another Merrill CDO. The problem? Too few investors had the time, resources, or inclination to do that much digging while Merrill Lynch had every incentive to just keep chugging along, dumping whatever it couldn't sell into the next CDO that rolled off the assembly line.

The Chickens Come Home to Roost

For centuries, the coronation of a new pope in the Roman Catholic Church was accompanied by an odd custom. As the new pontiff, arrayed in all his glory, walked toward St. Peter's Basilica, the master of ceremonies would halt the procession three times, fall to his knees, and raise a small silver platter on which burned a piece of cloth. "Sic transit gloria mundi," he would intone, urging the new pope to remember that all worldly glories vanish in time. Unfortunately, no one was on hand to remind Wall Street that the laws of nature and the rules of gravity still applied to them. While rising interest rates and the perils of reckless lending to homeowners and leveraged buyout deals alike would be slow to register on the minds of Wall Street bankers (Gelband being one of the rare exceptions), within days of the Blackstone IPO being completed, it was clear that Wall Street was in for trouble.

Wall Street's investment banks and their leaders would end up paying a heavy price for their obliviousness. In March 2007, Bear Stearns proudly proclaimed in a proxy filed with the SEC that its ROE was among the highest of its key competitors. A year later, its ROE had slumped to 1.9 percent and JPMorgan Chase stepped in at the behest of the Federal Reserve to prevent the entire financial system from having to pay too great a price for the risks that Bear Stearns had taken to beat its rivals in the ROE sweepstakes. "I guess, in hindsight, you could say that was a bit of hubris," admits former

Bear banker Tom Casson. By the summer of 2007, Merrill Lynch had $31 billion in leveraged loans sitting on its books that it needed to sell, while Citigroup had another $57 billion—but there were no willing buyers. They were stuck owning securities that they had hoped to be able to sell to yield-hungry investors; now that the music had stopped, they were on the banks' balance sheets. "We did eat our own cooking, and we choked on it," John Mack later admitted to FCIC commissioners. One by one, buyout deals—some announced, some still being negotiated—began to fall apart.

The most dramatic change occurred on Wall Street itself. Bear would be absorbed by JPMorgan Chase, Lehman filed for bankruptcy, and Merrill sought refuge in the reluctant embrace of Bank of America, whose top executives reeled at the size of the losses they were expected to absorb along with Merrill's operations. (Eventually, Merrill's losses would be so large as to effectively erase the investment bank's profits for the last eleven years; those at Fannie Mae eradicated twenty-plus years' worth of profits, according to calculations presented by Kyle Bass of Hayman Advisors LP to the FCIC.) Only later did it become public that Bank of America CEO Ken Lewis wanted to use those enormous write-offs as a reason to walk away from the deal, which undoubtedly would have led to Merrill's filing for bankruptcy protection. Only thinly veiled threats from Bernanke and Treasury secretary Hank Paulson kept him onboard, and by the fall of 2009 he had been fired as chairman of the company (by shareholders, at the company's annual meeting) and forced to step down as CEO (by the board of directors).

Lewis wasn't the only casualty. John Thain resigned after negotiating the sale of Merrill, although he soon returned as CEO of CIT Group, a commercial lender that had filed for bankruptcy in 2009. John Mack, exhausted by the effort to save Morgan Stanley, announced his decision to retire as CEO, although he stayed on as chairman. Across Wall Street, bankers whispered that the chaos of the previous two years had contributed to the sudden death at age sixty-one of Lazard's Bruce Wasserstein. The legendary deal maker died two days after being admitted to the hospital with an irregular

heartbeat in October 2009. And as for Richard Fuld, who had ousted Mike Gelband for not being a team player? Months after his firm collapsed, a sleepless Fuld spent the evenings wandering through his mansion in Greenwich, Connecticut, a community that was also home to many of the hedge fund managers who were among his firm's biggest and most lucrative clients. "How did it all go so disastrously wrong?" he wondered.[17]

There would be no more record-setting deals from which the surviving institutions could reap big fees. Among the last to collapse was the massive $48.5 billion proposed leveraged takeover of giant Canadian telecom concern BCE Inc. by a group that included the veteran buyout firm KKR. Announced only days after the Blackstone IPO, the transaction would have become the largest leveraged buyout in Wall Street history. Instead, it staggered along, half alive, as bankers and buyout firms tried frantically to pull off the deal in the months that followed the demise of Bear Stearns. The events of September 2008 were the last straw; the BCE deal was formally laid to rest two months later.

"Old" and "new" Wall Street suffered equally in the downturn and in the subsequent market chaos that accompanied the "deleveraging," as the process of unwinding all the complex debt instruments and structures was referred to. At the New York Stock Exchange, the lack of leverage started to show up in the shape of declining trading activity by hedge funds, the exchange's most lucrative group of clients. Thanks to that trend (as well as ongoing concerns about competition at home and in the exchange's new European business), NYSE Euronext's shares were trading at $36.62 at the time of this writing, down from their $81 first-day price. Blackstone, for its part, was changing hands for a mere $14.95 by the spring of 2010. Citigroup, a stock worth more than $50 a share in early 2006, could be picked up for less than $1 a share in early 2009. Veteran bankers were fleeing to join start-up firms, fearful of regulation that would limit the scope of their activities or even—heresy!—the size of their bonus checks. Wall Street was on the verge of yet another transformation. What remained unclear was perhaps the most important question of all: whether this would

return the Street to its roots as an intermediary or carry it further away from its core function as the money grid.

PART II

GREED, RECKLESSNESS, AND NEGLIGENCE: THE TOXIC BREW

On Tuesday, September 16, 2008, the major players in the unfolding financial crisis gathered in the Oval Office at the White House in order to brief President George W. Bush on the magnitude of the catastrophe that was looming. Treasury secretary Henry Paulson warned the president that, only days after Lehman Brothers had filed for bankruptcy and Merrill Lynch had sold itself to Bank of America in a deal arranged over the course of a weekend to prevent itself from following suit, insurance giant AIG was now teetering on the edge of collapse. "How have we come to the point where we can't let an institution fail without affecting the whole economy?" Bush wondered aloud after listening to his economic and market advisors lobby in favor of a bailout for AIG.[1]

The answer lies in a toxic blend of three elements, all of which were part and parcel of Wall Street by the beginning of the twenty-first century and all of which flowed from the same cultural breakdown on Wall Street itself. Individually, each could have damaged the ability of Wall Street to fulfill its core function effectively and created immense stress on the financial system as a whole, and each is addressed in a separate chapter in this section. But they evolved and reached an apogee almost simultaneously. Together, they would prove to be a recipe for disaster.

All three revolve around human behavior, more specifically on the kinds of incentives that exist on Wall Street to take foolish risks and the disincentives that should be in place to keep that risk taking within reasonable limitations. "The mixture of unlimited capital, limited liability, and incentive compensation inevitably led to testing the levels of risk," veteran banker Peter Solomon told FCIC commissioners. "It might be argued that public ownership and the compulsion to increase earnings per share propels employees towards greater risk." Especially when risk taking is so lavishly rewarded: Wall Street's pay packages rapidly became one of the biggest and easiest targets for its critics, not least because they made bankers who often were no more than moderately intelligent human beings into multimillionaires. "I know my limitations; I know I'm bright enough, but I'm no genius," says one former senior

banker who toiled at Lehman Brothers and other firms. “Certainly, many of the top guys were only just of average intelligence. But they were being paid for being ruthless and taking on as much risk as possible. The goal was to beat Goldman Sachs at its own game. It was clear to us all that the closer we could come to doing that, the more likely we were to walk away with tens or hundreds of millions of dollars, rather than just become single-digit millionaires.”

Even if Wall Streeters were encouraged to behave with reckless abandon, as long as they generated higher and higher returns on equity, it was still possible for the CEOs and directors of any of the investment banks or institutions such as Citigroup to apply a counterweight to any irrational exuberance that might bubble up as a result. Risk management had been a buzzword across Wall Street for decades. The 1998 collapse of Long-Term Capital Management should have highlighted the vital role that risk management could play in helping a financial institution avert catastrophe, both for itself and for the financial system. Alas, while Wall Street firms paid lip service to risk management, in practice they tended to rely too much on models that even their architects admitted were full of flaws. The problems at the rating agencies were just as bad, if not worse: despite their role as the protector of institutional and individual investors, both Moody’s and Standard & Poor’s had done a shoddy job of designing models that could cope with the most basic possible scenarios. Standard & Poor’s, for instance, admitted to one major player that its housing-price model couldn’t cope with negative numbers; if housing prices declined nationwide, the model would be useless. Even when the models were relatively robust, those using them massaged them to produce the results that were needed, or presented the results in a way that was calculated to get their audience to agree that the risk was manageable.

Jaidev Iyer now is the managing director of the Global Association of Risk Professionals (GARP); his former job was as head of operational risk management at Citigroup. In that role, he watched leaders at Citigroup develop risk management models showing that the bank’s capital was adequate to cover all possible

scenarios, with a 99.97 percent confidence rate. “Think about that. What they were really saying was that the capital was adequate for all but three years out of every ten thousand years!” Iyer understands the reason for Citigroup’s arrogance. “To get a double-A credit rating from Moody’s meant that you had to have that much confidence that your capital was enough to ride out any shocks, and Citigroup wanted that rating” because it would ensure that the company was seen as a stable, solid institution and thus cut funding costs. The problem was that Citigroup was basing its high confidence level on only four or five years’ worth of data. “That doesn’t begin to be enough to tell you what will or could happen, especially when you are dealing with markets and products and strategies that didn’t even exist a decade ago,” Iyer says.

Still, just as it was in the interests of Wall Street’s bankers and traders to take as much risk as possible in hopes of earning outsized bonuses, so it was in the interests of their top managers and even their boards of directors to egg them on rather than rein them in. When Bear Stearns went public in 1985, Wall Street’s investment banks had an average of $258,677 of capital for every employee. If that figure were merely adjusted for inflation, by 2000 it would have been about $540,000. In fact, by that year Wall Street had more than $1 million in capital for every employee, and as much as $3.5 million at some firms.[2] The pressure was on for those employees to make all that capital pay off by finding new ways to earn returns. And the way to do it wasn’t by becoming more cautious and risk-averse. Behaving like that wouldn’t help Lehman, Merrill Lynch, or Citigroup become the next Goldman Sachs. Rather, they needed to out-Goldman Goldman by taking on more risk.

None of that would have mattered had Wall Street had any effective adult supervision. What the money grid needed in order to protect it from the consequences of the greed, ineptitude, and folly within Wall Street’s institutions was a team of well-compensated, intelligent, and aggressive outside regulators monitoring what those people were getting up to and keeping them honest. And those regulators needed backup from legislators willing to give them both

the resources and the political capital they needed to get the job done.

Instead, the money grid got a regulatory mess: a cat's cradle of agencies with responsibilities and mandates that sometimes overlapped and sometimes clashed. All too often, that web of regulatory supervision left large and increasingly significant parts of the markets, such as derivative securities, almost entirely uncovered. And their staff members—whose ambition, in some cases, was to stop guarding the henhouse for less than $100,000 a year and quintuple their annual income by joining the foxes in devising new ways to raid it—too often lacked motivation, direction, or support from their political masters.

"Perfect storms happen when you create the opportunity for them to do so," says Iyer. Teaching future risk managers, he likes to use as a case study the Titanic—the "unsinkable" boat that sank less than three hours after hitting an iceberg in the North Atlantic, taking more than 1,500 passengers to a watery grave. Had Titanic's builders and captain not been so convinced that their vessel was unsinkable, had there been enough lifeboats, had the weather been better (enabling the lookout to spot the iceberg), or had the iceberg not brushed alongside Titanic's hull (damaging multiple watertight compartments), the death rate might have been much lower. While it is unclear how many actual deaths can be attributed to the disastrous Wall Street events of 2008 (many bankers tell stories of acquaintances who opted to commit suicide when their firms collapsed or they were laid off as a result of the cost cutting that eliminated more than 300,000 jobs in less than a year), the Street's great meltdown has certainly had a disastrous impact that has stretched well beyond its boundaries, all because the checks and balances that should have prevented the disaster either weren't functioning or weren't even in place to begin with.

Everyone was focused on what Wall Street could do for them, rather than on what they needed to do to maintain the health and integrity of the money grid. The bankers wanted more interesting jobs and career paths, punctuated with lavish paydays. On reaching the corner office, they needed and wanted to beat Goldman Sachs

by generating bigger and better returns. Meanwhile, the regulators wanted a peaceful and uncomplicated life; the politicians wanted votes. Collectively, they displayed a reckless indifference to the extraordinary risks that had become obvious before the credit bubble finally began to burst.

To prevent it all from happening again, like a bad nightmare that we can't escape, we need to do more than get angry about how much Wall Street bankers take home each year in their bonus checks. We need to understand how each part of this behavioral dynamic contributed to the crisis, and find a way to re-create effective checks and balances that encourage the right kind of risk taking but discourage some of the rash excesses of recent years.

By the time the final bill is presented to Congress, the cost of the financial industry's bailout may top $2 trillion, by many estimates. The immediate catalyst for that massive rescue attempt may have been fear of what would happen if those who should have protected the money grid allowed it to sink like the Titanic. But the reason the bailout, however distasteful, was unavoidable is the same reason that it behooves all of these interested parties to find real solutions to the problems presented by compensation policies, risk management failures, and regulatory shortcomings: the fact that we need a functioning financial system. In all three, participants placed their own interests ahead of those of the financial system. If Wall Street—the money grid—is to survive future shocks, we can't afford to have that happen again.

CHAPTER 5

"You Eat What You Kill"

At first glance, David Rubenstein and John Whitehead seem like unlikely party poopers. Both men had made billions of dollars by rising to the top of the heap on Wall Street and had overseen two of its most powerful institutions. But as the Street celebrated a record-breaking 2006 and plotted how to earn still more fees and proprietary trading and investing profits in 2007, both Rubenstein, cofounder of the Carlyle Group, one of the largest private equity firms, and Whitehead, the former senior partner of Goldman Sachs, were worrying publicly about Wall Street's addiction to easy money, particularly in the form of multimillion-dollar bonus days. "Greed has taken over," warned Rubenstein at a private equity conference in the spring of 2007.

The eighty-five-year-old Whitehead was even more forthright in an interview with Bloomberg News reporters that May. He blasted the lavish pay packages at his former firm, where the average employee had pocketed $621,800 in 2006. Goldman's top traders walked away with tens of millions of dollars apiece, and even secretaries could count on a yearly bonus worth a few thousand dollars. That was double what Goldman employees had earned a decade earlier, before the firm had gone public, and 20 percent higher than 2005. It flew in the face of the fact that Goldman traditionally had been more restrained when it came to compensation than many of its Wall Street peers: its bankers were told firmly that a large part of the value they generated was because of Goldman's brand name rather than their individual efforts. Until they became partners, they learned, they would have to reconcile themselves to viewing the firm's high status as part of their

"compensation."

But by 2006, even Goldman seemed to have joined the bonus party. Not only were the denizens of Wall Street—and Goldman Sachs in particular—already far richer than their counterparts on Main Street (the national wage grew an average of 2 percent that year), they were getting even richer at a far faster clip. Whitehead said he was "appalled" that Goldman was leading the way "in this outrageous increase" in Wall Street compensation. He tried to convince Goldman's board to donate $1 billion of its record $9.5 billion earnings for the year to charity; he had even turned to the Bill & Melinda Gates Foundation for help devising some specific proposals about how such a philanthropic donation could be deployed. Goldman's active partners weren't interested, however: their priority was on maximizing returns to shareholders, and a massive philanthropic donation would harm, not help, that cause. Besides, why run the risk of losing its top producers to rivals by donating part of their bonus pool to charity?[1]

Whitehead's concerns were the exception rather than the rule in 2006. Few on Wall Street demurred when they were handed six-, seven-, or even eight-figure bonus checks that year. Anyone outside the Street who voiced concerns about investment banking compensation policies or levels was largely dismissed as an envious crank who either didn't have what it took to survive on Wall Street or had chosen a field that wasn't as lucrative or glamorous as investment banking. Certainly, Dow Kim, co-head of investment banking at Merrill Lynch, likely wasn't second-guessing his own 2006 Wall Street pay package any more than were the lavishly paid Goldman Sachs bankers of whom Whitehead complained. That year, Kim pocketed a salary of $350,000 for his efforts, a comfortable sum, if modest by Manhattan standards. But Wall Street salaries are just the tip of the iceberg; in gratitude for his 2006 performance, Merrill's compensation committee awarded Kim a cash bonus of $14.5 million and another $20.2 million worth of stock in the investment bank. His total compensation package was worth $35 million, one hundred times his nominal salary.[2] But then, Kim was a particularly valuable employee for Merrill Lynch:

it was he who, after the departure of Christopher Ricciardi (the man who had pushed Merrill into the forefront of the CDO league tables), kept Merrill's CDO creation machine churning at an ever-faster rate.

The Rainmakers Rake It In

As Wall Street's transformation proceeded during the 1980s and '90s, investment bankers who could dream up products and generate outsized profits were increasingly valuable to Wall Street institutions. According to one study of Wall Street compensation, bonuses and salaries became "excessively high" in the mid-1990s and stayed that way until 2006.[3]

Wall Street put a premium on creativity and innovation, at least within those firms that were intent on beating their rivals and maximizing their profits. The result was a jump in demand for investment bankers with more sophisticated skill sets—the ability to structure, evaluate, and trade junk bond transactions, say, rather than just handle the lower-risk Treasury bond trades. However much as Wall Street's elder statesmen might lament the fact, the relentless quest for innovation and new sources of growth inexorably had created a war for talent and fueled runaway growth in salaries and bonuses. Taking a hard line on compensation would have required an investment bank to tacitly acknowledge that they were prepared to forfeit growth—an unacceptable alternative.

At Merrill Lynch in 2006, few employees were more important than Dow Kim, who promised to do whatever it took to keep Merrill ahead of its rivals in the battle to capture the largest possible chunk of the ever-growing market for spinning mortgage securities into CDOs.

In 2006, Merrill created $147.2 billion of new mortgage securities-backed CDOs, up from $90.3 billion the previous years; some of the more complex structures could earn Merrill fees of as much as $15 million for each $1 billion CDO. That was enough to make Merrill Lynch the top underwriter of CDOs in the country,

from number fifteen in 2002; in the 2002–2007 period, it underwrote one hundred of these vehicles, compared to only seventy-three for Citigroup. And for the folks at Merrill Lynch, that was something to celebrate, rather than worry about. “Every time we went to meet with someone at Merrill, they would speak in hushed, reverential terms about this guy, Dow Kim,” says Mark Vaselkiv of T. Rowe Price. “He and guys like him were leading their firms and Wall Street as a whole into the brave new world of mortgage-based derivatives, and his team worshipped the ground he walked on, it seemed, at least in part because he was making them so much money.”

It was only a matter of months before problems surfaced. Kim told the CDO team to do “whatever it takes” to hang on to market share and seize the lead in the race for the top spot in the league tables, according to allegations by former employees made in lawsuits filed after Merrill’s sale to Bank of America. Even as Kim pocketed his gargantuan bonus, he must have been aware that his CDO assembly line was working almost too well. Kim’s division was turning out more mortgage-backed securities than the firm could structure into CDOs and creating more CDOs than it could sell quickly. By 2006, there were few “real money” investors left in the market, the Financial Crisis Inquiry Commission would later point out; data showed that 80 percent of the mezzanine tranches of CDOs that Merrill originated in late 2006 and into 2007 were sold to other CDO managers. As a result, more of the increasingly risky securitized assets were left sitting on the investment bank’s own balance sheet; by the end of 2006, Merrill had $44.5 billion in mortgages, CDOs, and other related assets sitting on its balance sheet, up from $29.2 billion the previous year and only $15 billion at the end of 2002.[4] At the same time, it was becoming harder and harder to find a counterparty willing to let Merrill hedge the risk that the value of those assets would slump before they could be sold to investors. In May 2007 Kim left the CDO-creation machine he had structured to others to run, and set out to launch his own hedge fund.

Everyone involved in creating, launching, and marketing the

CDOs knew that the size of their bonus depended on keeping the machine humming as rapidly as possible. There was no incentive to holler stop.

Outsized Pay and Outsized Losses

But by late summer 2007, it was clear that the securities on Merrill's balance sheet contained a lot of subprime mortgage assets on which the firm would have to record large losses as their values plunged. Sure enough, in October 2007, Merrill slashed the value of the CDOs and subprime mortgages still on its books by an astonishing $8 billion, nearly double the sum estimated only a few weeks earlier. By year-end 2007 it had announced another $11.5 billion in CDO-related write-downs, leaving Merrill with the largest loss in its ninety-three-year history, and the first it had recorded in nearly two decades. In only months, any gains Kim and his team had made for Merrill over the years they had toiled there while pocketing small fortunes for themselves had evaporated. Ultimately, Merrill's losses would be large enough to swallow eleven years' worth of profits.[5]

Not surprisingly, the outsized paydays reported by Kim as well as Wall Street CEOs such as Merrill Lynch's Stan O'Neal—who walked away with $160 million or so of deferred compensation, stock options, and other goodies as well as years of lavish pay packages despite presiding over the carnage—touched off outrage and protest that has stretched from the Oval Office right down to the folks in the streets. How could Wall Street folks be paid so well for doing so badly? And what does any banker do in a single year that is worth a $14.5 million bonus—at least, what that is legal?

But the incomprehension is mutual. In Wall Street's worldview, its inhabitants put in long hours doing increasingly complex jobs that few others have the ability to handle, even if they are willing to tolerate the extraordinary stress and the complete absence of any kind of work-life balance. Naturally, the argument goes, they are well paid for those efforts. Even long after Wall Street's

compensation policies became a hot-button issue, some prominent individuals were still willing to defend them. Thomas Donohue, president and chief executive officer of the U.S. Chamber of Commerce, admitted that the bonus payments made by Goldman Sachs and other firms in 2009 may seem "obscene" to the average person—and perhaps even to himself. But Donohue still believed they were justified, he said in early 2010. After all, those lavish pay packages were awarded to "very unique kinds of people," he explained to a reporter. "They are like mad scientists. They are all mathematicians and they are very mobile. They can go to private equity and hedge funds."

One of those financiers, Jake DeSantis, an executive vice president at AIG, spent a year helping to dismantle the company in the wake of its toxic derivatives blowup. When he discovered that Congress, President Barack Obama, and Andrew Cuomo, New York's attorney general, to name just a few, were determined that he shouldn't receive the bonus AIG had promised him, DeSantis blew his stack and published his resignation letter in the New York Times. "[We] have been betrayed by A.I.G. and are being unfairly persecuted by elected officials," he railed.

The response was both immediate and predictable. On the New York Times website, where DeSantis's letter had been published in its entirety, a steady stream of responses flowed in. Why, wondered a reader named Rob, did DeSantis fail to grasp why his "retention payment" (undisclosed, but potentially around $750,000) was "so offensive to taxpayers in a country where the median family income is approximately $48,000 [?] … Please clean out your desk. Security will take your key and show you to the door." Another respondent, Tim Burke, pointed out the flaws in DeSantis's comparison of himself to a plumber who is penalized when an electrician burns down the house that they have both been working on. If both the plumber and electrician were hired by the same contractor and the plumber was present when the electrician "laid a trail of flowing gasoline between all the homes in the neighborhood, then the plumber might reasonably expect his own payment might be at risk." And someone called only IW took a jab

at the lifestyle of the rich and (in)famous bankers. “Even if this guy was not in the CDS [credit default swaps] business himself, where does he think that the money was coming from to pay for his 10 cars and house in the Hamptons? … I am sure you can survive on $80 a bottle champagne rather than the stuff you are used to, Jake.”[6]

DeSantis wasn’t alone in triggering public outrage. After bankers lost so many billions of dollars so rapidly, their lavish lifestyles came under harsher scrutiny. In one spectacularly ill-considered move, John Thain, after replacing O’Neal at the helm of Merrill Lynch, cheerfully signed off on a now-infamous $1.2 million redecoration of the firm’s CEO suite of offices; the payments included $1,400 for a parchment “waste can” and $13,000 for a chandelier for a private dining room. Then, only weeks before the emergency takeover of Merrill Lynch by Bank of America was completed, Thain rushed through $4 billion in bonuses to Merrill executives, to prevent them from fleeing to a better-capitalized rival, bolting to a hedge fund, or starting their own boutique.

No one on Wall Street doubted Thain’s abilities; after all, he won partnership at Goldman Sachs and reinvented the New York Stock Exchange before snatching a kind of victory from the jaws of defeat for Merrill by negotiating the Bank of America deal. And it’s certainly true that many Merrill executives—like those elsewhere on Wall Street—had managed to generate profits for their firms despite the extraordinarily difficult market environment and by Wall Street standards deserved some kind of reward. But jaws dropped when word leaked out that Thain wanted Bank of America to recognize his achievement in pulling off the merger by awarding him a $10 million bonus. Few of Merrill’s massive problems had occurred on his watch, of course, but Thain had earned $84 million in compensation the previous year; Merrill had even reimbursed him for a bonus that he had forfeited by walking away from his prior job at the New York Stock Exchange to join Merrill. Was Thain oblivious to the degree of public outrage? It certainly seemed so; word leaked out that he had calmly informed Bank of America executives, in connection with the proposed bonus, “I really think

I'm worth that."[7] (In the end, he didn't get it; belatedly recognizing the degree of public outrage, he waived his bonus for the year.)

Had Wall Street gone insane? Possibly. Certainly the Street's compensation system had gone badly awry, although the problem had less to do with the sheer magnitude of the salary and bonus checks than those on Main Street might have believed. True, those were exorbitant, and some people on Wall Street sheepishly admit they had a tough time explaining their jobs and their compensation to family members even before the subprime debacle—and not just because the world of finance was so complex. The real problem was that as Wall Street investment banks had morphed from closely held partnerships into publicly traded entities, their compensation structures had remained stuck in the past. Paying out 40 percent or more of each year's revenue in salaries and bonuses had been the norm within a partnership, and remained standard within the new publicly traded entities. But that compensation model didn't take into account the changes that had occurred within the financial services industry.

Wall Street had once been a fragmented business, with a large number of firms vying with each other for market share and none of them in a position to shake the system to its foundations on its own. But by the late 1990s, Wall Street had become a business dominated by global behemoths formed through a series of mergers. Even when the businesses themselves remained relatively small, as Bear Stearns and Lehman had done, they became critical to the financial system because the linkages between those firms and the rest of the system grew exponentially. At the time of Lehman's collapse, for instance, the investment bank had more than a million derivatives trades outstanding; at the other end of each was another financial institution of some kind.[8] All but the smallest and most isolated Wall Street firms are now "systemically critical," as Fed chairman Bernanke has phrased it; each one plays a much greater role in the health of the system than ever before. In other words, Wall Street institutions had become too big to fail, a phrase that is now repeated endlessly by everyone discussing the future of the financial system. In that environment, risk taking wouldn't be

restricted by the usual concerns of collapse—there was no moral hazard. Even firms that publicly proclaimed that they didn't believe a financial institution should be so systemically important were quietly confident that their bank was among that elite group that would receive some kind of assistance from the powers that be should it become necessary.

But while Wall Street had changed, increasing the level of systemic risk, the compensation system was set up in such a way that it encouraged players such as Dow Kim to boost that risk level even further by using leverage or putting a firm's own capital on the line in hopes of generating higher returns for shareholders. "We lost the checks and balances, a system that provided a kind of curb on excessive risk taking, when we moved away from the partnership model," argues John Costas, the former UBS investment banking head. Once, even those who hadn't yet become partners in a firm, the deal makers and traders such as Dow Kim, would have been very conscious of the risks they were running, since it was their own capital—past, present, and future—that was on the line, argue Costas and other Wall Street veterans. In contrast, today's bankers were largely employees, with every incentive to maximize risk taking and few, if any, to curb that risk.

True, many Wall Street employees, from the top all the way down the line, did get a majority of their annual pay in the form of stock, options, or restricted stock, or opted to keep the bulk of their savings in their own firm's stock. At Bear Stearns, for instance, some 30 percent of the company's stock was owned by employees, whether in the form of stock grants made during the annual bonus payment season or direct or indirect investments. Owning stock didn't give bankers any sense of being the company's owners, however. The capital that they were using to place their bets—structuring riskier leveraged loans for private equity clients and riskier CDO structures that would sit on their own balance sheet until they could find a willing buyer—didn't belong to them, they felt. "There was no question that we saw it as other people's money," says one former senior banker.

In fact, employee ownership may have backfired. Just as had

occurred at companies such as Enron and WorldCom in the 1990s, employees were motivated to take on more risk rather than curb their risk appetite as the market environment became more difficult. “We wanted to boost the share price” so that their holdings were worth more, the banker says. “The risk managers were the guys that tried to stop us from doing that.” Aggravating the problem, that banker adds, was the fact that Wall Street firms increasingly began to see themselves as being more accountable to the demands of shareholders than to the needs of clients, at least at the top levels of the company, where policy was made. “Who were our clients? They were ourselves first—because half the revenue goes to us—and then the shareholders.”

Swinging for the Fences

In a nutshell, Wall Street’s compensation policies rewarded traders, investment bankers, and even CEOs for taking enormous risks in exchange for enormous profits rather than for keeping an eye on whether the risks they were running made sense for either the firm itself or the financial system as a whole. “It’s that asymmetry that’s at the heart of so much that has gone wrong,” says Seth Merrin, cofounder and CEO of Liquidnet, a next-generation trading system. Merrin began working as a trader when he graduated from college with a political science degree and couldn’t even find a job as a waiter. Within a few years, he was running a risk arbitrage desk and pulling down a Wall Street–sized salary, but already he was aware of the gap between the sums he and his colleagues were paid and the value they delivered to customers. “There was such a mystique to Wall Street; everyone saw it as so automated and efficient, as if it were a supermarket,” Merrin observes. “But it wasn’t, because it didn’t have to live on supermarket profit margins. And people on the Street there were paid for generating wider profit margins, not for lowering costs to customers.”

In the late 1980s, Merrin decamped from mainstream Wall Street to launch his first “alternative” trading network, an electronic order

management and routing system. He assumed that as Wall Street firms came under pressure to cut trading costs, that new discipline would spread to other areas of the business, including compensation. Instead, he saw the rate at which bonuses climbed escalate still further and become more out of whack with compensation policies on Main Street. “Everyone is their own profit center within a Wall Street firm and you eat what you kill,” he explains.

Compensation has little to do with how well the investment bank’s clients fare, much less how the risk taken by the investment banker to earn those hefty profits affects the financial system. Sometimes it doesn’t even matter how the investment bank itself performed, as was the case with Merrill Lynch in 2008, when hundreds of employees pocketed million-dollar bonuses in a year in which the company and the financial system nearly collapsed and were saved only by drastic action. A federal judge who later refused to sign off on a deal between the SEC and Bank of America (which acquired Merrill Lynch and whose top brass agreed to the bonuses) regarding these bonuses wondered aloud, incredulously: “Do Wall Street people expect to be paid large bonuses in years when their company lost $27 billion?” The answer was yes. “There’s a big incentive to swing for the fences,” says Merrin. “Should they pull it off, they are compensated extraordinarily well.” The only people who suffer are those whose direct actions cause the losses. Even then, “if they lose a couple of billion the next year, well, they don’t give back what they earned the previous year. All they are is fired and rich.”

It’s normal in American society for those who are successful to be well paid and for those who become stars in their field to be lavishly rewarded. True, some gripe when a major league baseball team promises a superstar pitcher the equivalent of thousands of dollars for every ball he hurls from the mound during the next three years. But by and large, Americans feel that if someone has performed well, she deserves whatever the going rate is for her services. As long as the pitcher hurls strikes, the grumbling remains muted.

Most of us have few problems when a successful cardiac surgeon makes millions or billionaires such as Bill Gates and Warren Buffett earn a place on the Forbes 400 list of the richest Americans. Perhaps we find that acceptable, or at least tolerable, because it reassures us that if we work hard and succeed, we too will be rewarded with mansions, yachts, art collections, fast cars, and $6,000 shower curtains or lots of whatever money can buy that we hanker after. But the ultra-wealthy can squander that tolerance: all that is required is for the average American to believe either that the wealthy individual has achieved those riches through some kind of fraud or deception or at the expense of the little guy on Main Street. Just ask a corporate CEO convicted of cooking the books or a star baseball player accused of taking steroids. And Main Street's tolerance for Wall Street's riches has always been a bit more fragile than it is in the case of the entertainment industry, sports, or even the rest of the business world, perhaps because so few people understand why packaging up mortgages and redistributing them is worth so much money. Like him or loathe him, at least we can all gape at Donald Trump's buildings and understand where the money comes from to fuel his flashy lifestyle. When it comes to the bankers who structure—and restructure—Trump's loans, however, the value of their services is harder to grasp for anyone outside Wall Street's magic circle.

But while populist outrage focuses on the dollar amounts involved, it is actually the incentives at the heart of the compensation system that produce lethal results such as the near-total collapse of the financial system in 2008. If our hypothetical exorbitantly paid cardiac surgeon has a 90 percent success rate among his patients, saving lives daily, then most Americans would agree he's entitled to every dollar he earns. But if he charges more than his peers and has a lower survival rate, grumbling and outrage will follow. And if half his patients are dead at the end of a year, odds are he won't even be able to retire to enjoy the income he has earned so far. The families of those patients will sue him, the medical association may yank his license to practice and, depending on the degree to which he was negligent, he could even face

criminal charges. There is, built into the medical system, a series of incentives and disincentives that link hard work, skill, and the results of the surgeon's work to compensation.

Now, let's assume that the compensation policies that prevailed on Wall Street in 2006 were the rule in medicine. That hypothetical surgeon would have been paid more for every operation he performed, regardless of the risk to the patient's life. Indeed, the higher risk the surgery, the greater the fee he could have charged, as long as the patient survived for at least a few months and as long as he could convince more patients to go under the knife. Should half of those patients die the next year, the hospital might fire him, but he'd probably leave with a golden handshake; the odds that he would be sued or face criminal charges would have been minute. In many cases, he could move to another hospital or set up his own medical practice and attract new patients. The problem with Wall Street's asymmetrical compensation is actually worse. A surgeon has to buy malpractice insurance, footing the bill for his own errors and those of his peers; when successful plaintiffs drive him into bankruptcy, they can collect the balance of any sums owing from the insurer. Alas, Wall Street doesn't have to purchase malpractice insurance; there isn't even a sense that there is a duty of care to the "patient"—whether that patient is the client or the financial system. And so, as we have just witnessed, taxpayers end up footing the bill for Wall Street's errors of judgment.

Of course, there was the FDIC, which was responsible for "insuring" banks and thrifts—or at least their depositors—against the collapse of an institution. But that covered depositors' assets only up to a certain sum; it wouldn't affect banking counterparty relationships. And even so, as an irritated Mike Mayo pointed out to the FCIC in early 2010, FDIC members—the banks—hadn't had to pay anything in the way of premiums for the ten years leading up to 2006, since the insurance fund was believed to be robust enough. That, he said, is "analogous to an auto insurance company not charging premiums until somebody had an accident or a life insurance company not charging premiums until somebody dies."

On Wall Street, most bankers and traders begin doing the bonus

math toward the end of the year. But their calculations aren't based on such issues as the strength of their company or their earnings relative to the risks they have taken, much less how well their customers have fared after consuming (purchasing) the products they have created, or their role in maintaining or hurting the financial system as a whole. They are looking at a far simpler equation: how much money did their business division make, and how much of that did they themselves contribute? "If someone generated $10 million in fees last year and got paid $800,000, they expect that ratio to stay pretty much the same year over year," explains one former senior banking executive. "If that guy goes to $20 million the next year, he expects to be paid $1.6 million at least. And he gets really irritated if his boss tells him he's only going to get $1.1 million."

That compensation system creates a series of perverse incentives, the executive explains. If it costs that individual $2 in (company-paid) expenses to make $1 in revenue, he doesn't care, because he's not being paid to control costs but to generate revenue. "And if someone tells him he can't spend that much, he'll probably fight for the right to run his business division as he sees fit." Similarly, if half of the business he generates is higher risk and lower quality, that also is irrelevant: every dollar of fee income is treated the same for the purposes of computing compensation. "I used to tell everyone I met that whatever they were earning, if they were on Wall Street, they were automatically overpaid," says the executive. Not surprisingly, he says, few of those he worked with agreed with him, his personal assistant (who took home $100,000 a year plus a bonus) among them.

In that context, it's not shocking that Dow Kim was so well rewarded for boosting Merrill's exposure to CDOs, even as the percentage of those packaged securities containing riskier mortgage loans to subprime borrowers increased every quarter. Joseph Stiglitz, a professor at Columbia University, summed up the conundrum in his testimony to the House Financial Services Committee in October 2008. "The problem with incentive structures is not just the level but also the form," he warned. As

they stand, he pointed out, they are "designed to encourage excessive risk taking and shortsighted behavior."

Bonus Junkies

It wasn't always this way. Once upon a time, working on Wall Street was about as lucrative as any other profession that demanded an advanced education and a hefty time commitment from its practitioners, such as the law or medicine. Only a handful of people at the pinnacle—such as J. P. Morgan himself, who as a financial industry tycoon was as much a user of the system as he was a part of it, earning massive profits from restructuring businesses and entire industries—found Wall Street a ticket to great riches. At Morgan Stanley, bonuses rarely added up to more than a month or two's worth of salary for lucky recipients; a fraction of their annual salary.[9] For every J. P. Morgan, there were thousands of bankers toiling on Wall Street in relative obscurity, well paid but not lavishly so. In the words of former Morgan Stanley partner Fred Whittemore, the goal of investment bankers was to become "respectably rich in a respectable way,"[10] a phrase that was in tune with the 1930s pledge by Jack Morgan (J. P. Morgan's son) to Congress that the House of Morgan was committed to doing "first-class business in a first-class way."

By the 1980s, that approach to compensation seemed to be as much of an anachronism as Morgan Stanley's insistence on being the sole lead underwriter on any deal it did for clients. When Bob Greenhill's merger advisory group began generating hefty profits for the firm, resentment began to build among other partners at what they perceived to be Greenhill's arrogance. "Greenhill should remember that whatever success he has comes from the franchise," one of the firm's partners griped.[11] Increasingly, however, that wasn't true; a star banker, analyst, or trader could become his or her own franchise, as Greenhill and later figures such as controversial technology banker Frank Quattrone proved, hopping from one firm to another with full confidence that their clients would follow

them.

Loyalty shifted from the firm and the franchise to the department. Ultimately, at many firms the individual banker or trader owed his loyalty to that department only as long as it was profitable to do so. (The exception was at firms that retained a strong culture, such as Goldman and, until recently, the old J. P. Morgan.) As that process continued, Lou Gelman, the former Morgan Stanley banker, reflects wryly, Wall Street became more about doing any class of business for first-class pay, while bonuses had become multiples of annual salaries rather than fractions. "Nobody on Wall Street gets paid for turning down a deal," he says. "What are you going to say at the end of the year when your buddies ask what your bonus was? No one says, 'Oh, I turned down these five deals because I didn't think they were good for our franchise'! Because what was good for the franchise wasn't turning deals down, it was making more money." And that franchise wasn't always the institution itself, but some subgroup within it, from proprietary trading to telecommunications banking. In years when newly public companies lost money and saw share prices plunge, employees in profitable subgroups still pocketed bonuses. It was the payment of just that kind of bonus in 2008 that sparked such outrage.

And as the 1980s drew to a close, the value of those bonuses began to move into nosebleed territory. In the first stages of the bull market, during the late 1980s, the average Wall Street bonus remained less than the average salary—ranging between $14,000 and $15,500 a year. It wasn't until 1986 that researchers found that the average annual earnings of an investment banker began to exceed those paid to another group of professionals where skill and experience is also prized—engineers.[12] That gap continued to widen. Suddenly, in 1991, the average bonus doubled to $31,100, and continued to climb before peaking (for now, at least) at $190,600 in 2006. (In 2010, the average bonus fell back to $128,530, as Wall Street boosted base salaries in response to new regulations.) Over a seventeen-year span, bonus payouts to Wall Streeters grew at an average annual clip of 11.7 percent; during the same time frame, the rate of growth in the average wage declined

from around 4 percent to as little as 2 percent. Interestingly, the total bonus pool grew more rapidly than the average bonus, signaling that the benefits were going to the higher-compensated employees.[13] The growing Wall Street pay packages both contributed to the soaring cost of living in New York, and then, in a vicious circle, kept increasing to keep pace with that cost of living. By the late 1980s, in Manhattan at least (given sky-high real estate prices and the soaring cost of private school tuition), it was difficult for a senior banker to maintain his or her standard of living on salary alone, especially as it tended to stay relatively flat when compared to bonuses. Back in the 1970s, a Morgan Stanley partner could earn about $100,000 a year and financier Saul Steinberg bought one of the costliest apartments in Manhattan at the landmark building at 740 Park Avenue (formerly occupied by Mrs. John D. Rockefeller Jr.) for a mere $250,000. Today, only a Wall Street CEO or a handful of the industry's top producers can expect to earn the inflation-adjusted equivalent of $100,000 ($525,000 in 2009 dollars) in salary. At Merrill Lynch, for instance, the salaries of the six top executives in 2006 ranged from a mere $275,000 to $700,000 for CEO Stan O'Neal.

The apartment at 740 Park Avenue remained one of the city's most expensive, but someone such as Dow Kim would have had to pay out not two and a half times his annual salary (adjusted for inflation) but closer to a hundred times to purchase such a trophy property. In 2000, when Steinberg sold his apartment, a member of Wall Street's new elite, Blackstone Group's Steve Schwarzman, paid $37 million for it. (Adjusted for inflation, the 1971 purchase price would have been closer to $1.1 million in 2000 dollars.) Few on Wall Street were even in a position to fork over two and a half times their bonus payment to acquire the apartment. Years of outsized paydays at investment banks, hedge funds, and private equity funds meant that only a few investment bankers were now wealthy enough to contemplate such a purchase. (One of Schwarzman's newest neighbors is John Thain, who spent $27.5 million for his own duplex in 2006.)

Why have bonus payments and compensation grown so

exponentially? Ask anyone on Wall Street, and you'll get a list of reasons (today likely to be delivered in a rather defensive manner) that sound a lot like those advanced in Jake DeSantis's resignation letter. Bankers, they say, earn every penny of their money, thanks to their hard work, skill, and expertise. It's certainly true that the professional life of a Wall Street banker, like that of a professional athlete, tends to be a Hobbesian one—nasty, brutish, and short. Walk onto a Wall Street trading floor and you won't see too many gray heads among those bent over computer trading terminals. Trading is a young person's game (and still largely a young man's game); people burn out at a relatively young age. Even in the world of investment banking, if you're still at it in your mid-fifties, it's either because you're a genius and on the fast track to the CEO suite, or because you don't have anything else in your life that you'd rather be doing.

Tony Guernsey of Wilmington Trust points to another reason for the magnitude of the pay packages. "People want the best service, period; it's no different than having the best plastic surgeon or a barracuda lawyer. If you want to sell your company, you want to maximize the price. You don't care what he makes as long as you get more than you thought you would." In the late 1990s, one of Guernsey's wealth management clients approached him for help selling the magazine publishing company he owned. Guernsey and his client picked Steve Rattner, then the acknowledged chief deal maker at Lazard and a star media banker, to handle the sale. Rattner sat down with some twenty potential bidders, including S. I. Newhouse of Condé Nast, to discuss the company and the potential deal.

"The first lot of bids came back at between $60 million and $90 million, and Newhouse was the low bidder," recalls Guernsey. Rattner, orchestrating an auction among the five most likely buyers, sent a draft contract back to them with instructions to alter it as they wanted, warning them that any changes they made would represent their final bid. "Four bids came back—and Si [Newhouse] won it with the highest bid of $175 million!" Guernsey says, grinning at the memory. "And that is why Steve Rattner has always

earned the big bucks—he brings home the premium valuations for his clients."

Unfortunately for their clients, bankers like that may be harder to find on Wall Street these days. (Rattner himself decamped in 2000 and set up his own private equity firm before becoming President Obama's "car czar"; since leaving that past, he has paid fines to settle a series of allegations by regulators that he paid kickbacks to win business.) And as Wall Street has increasingly turned away from agency business—doing business as an intermediary for clients like Guernsey's—in favor of proprietary deal making and trading, it has become more difficult to point to excellent client service as a rationale for such enormous paychecks, especially since many of the bankers who still served clients did so at firms that were ramping up those proprietary activities at a far greater rate.

Tom Casson, the former Bear Stearns banker, still argues that he and his colleagues earned their bonuses by slaving, day in and day out, to deliver excellent results. "I would tell the new guys that anything less than perfection in a spreadsheet or a PowerPoint presentation earned them an F; it's the same standard of success as surgery," he recalls. But would Casson and his peers have had the platform on which to build a banking business—much less had the opportunity to be richly rewarded for their undoubted efforts—if it hadn't been for the fact that Bear itself was, as Casson acknowledges, a giant hedge fund? And even if Casson had recognized the degree of leverage on his parent firm's balance sheet, would he have questioned either that or his compensation? "Probably not," he admits. "I would have drawn comfort from the fact that it was the standard across the investment banking industry; everybody was doing it."

In fact, the real reason for the hefty paydays came to have as much to do with the need to retain their top performers as with client service excellence. (Certainly, the very common comparison to other professions, whether surgery or the law, doesn't hold water: although the jobs can be just as grueling and all require advanced education, only exceptional lawyers and surgeons will be able to earn seven-figure compensation packages, and then only

after a decade or two of experience.) Increasingly, private equity and hedge funds were cherry-picking the top performers at investment banks and inviting them to move to their corner of Wall Street, where bureaucracy and regulation was less arduous and where, when it came to compensation, the sky was the limit. After all, while Wall Street CEOs were making tens of millions—and suffering lots of headaches—hedge fund managers were raking in billions a year in profits for their firms, and up to hundreds of millions for themselves.

SAC Capital's Steve Cohen, one of the most famous hedge fund investors, lived in a modest home in Greenwich, Connecticut, for several years, even after leaving Gruntal & Co. in 1992 to set up his own hedge fund. (Early visitors to that home recall that Cohen and his first wife would bring plastic patio chairs into the living room to accommodate overflow guests.) But Cohen's lifestyle changed as his earning power increased exponentially; he pocketed first tens of millions, then hundreds of millions of dollars a year in both management fees and as his share of profits earned for investors in his hedge fund empire. (In December 2009, Cohen's first wife, Patricia, filed a lawsuit claiming that he had hidden millions of dollars of those riches from her during their 1990 divorce. A spokesman for Cohen, whose net worth is now estimated to be around $6 billion, called the allegations "patently false" and the case was dismissed by a federal court judge in March 2011.) That was a lot more than he would ever have been able to make at Gruntal, where he likely would have remained earning single-digit millions. In 1998, Cohen and his second wife, Alexandra, bought a 35,000-square-foot home in Greenwich that gets bigger with every year that passes (the couple requested permission to add an extra 1,100 square feet in late 2008) and offers its inhabitants and guests still more amenities.

Visitors report the Cohen mansion now includes not only an indoor swimming pool and an outdoor ice rink but its own Zamboni machine to keep the ice in pristine shape for impromptu hockey games. Indoors, the plastic chairs have given way to Cohen's art collection, which he has already spent close to $1 billion

accumulating. Most famously, that includes a fourteen-foot-long tiger shark pickled in formaldehyde, for which Cohen paid artist Damien Hirst some $8 million; he is said by those who know him to have dismissed the costs associated with renovating and then replacing the molting shark (some $100,000) as the equivalent (in Cohen terms) of a cup of Starbucks coffee. Just as startling as the flaking shark is a work that Cohen has displayed in a frozen container in his own office: a sculpture of a human head made out of freeze-dried blood by the artist Marc Quinn.[14]

Meanwhile, Cohen's protégé David Ganek had become a second-generation hedge fund wizard. Founding Level Global Investors in 2003, Ganek pocketed more than any Wall Street CEO in 2007 (between $70 million and $100 million, according to estimates by Trader Monthly) despite the relatively small size of his $2.5 billion fund. He is one of the new breed of Wall Streeters gravitating to 740 Park Avenue; he paid $19 million for the duplex that ITT chairman Rand Araskog once called home, making him a neighbor of Schwarzman and Thain. (Ganek closed down his fund in late 2010.) These days, 740 Park was looking more like a building designed for Wall Street; it boasted fewer captains of industry and scions of wealthy families among its residents.

For star traders at Wall Street investment banks, Cohen and Ganek were the guys to emulate. They could make far more money doing their own thing than those working at a Wall Street investment bank could hope to do over the course of their working lives. The investment banks were hardly oblivious to the threat: if they hoped to continue not just serving but competing with the biggest hedge funds and private equity funds, they realized they would have to fight to keep their most skilled traders and deal makers within their own walls. That meant rewarding promising newcomers and boosting salaries for a critical mass of veterans, and making sure they had as much capital as they needed to generate profits from proprietary deals and trades. After Vikram Pandit and two other senior bankers left Morgan Stanley to form the Old Lane hedge fund, and top M&A bankers Joseph Perella and Terry Meguid, among others, set up Perella Weinberg Partners LP, the

firm's new CEO, John Mack, offered an array of incentives to keep other employees from following their example. (Among other perks, Morgan Stanley's employees were now allowed to invest part of their annual bonuses in the firm's own hedge funds and buyout funds.) John Whitehead, at least, would have preferred Goldman Sachs to call the bluff of employees threatening to decamp to greener pastures. "I would take the chance of losing a lot of them and let them see what happens when the hedge fund bubble, as I see it, ends."[15]

Whenever Wall Street's compensation policies have rewarded short-term profit generation at the expense of the longer-term interests of the firm, its clients, or the system, it has led to abuses, risk managers and other analysts argue. Behind any rogue trader, from Nick Leeson (who brought about the collapse of Barings Bank in the 1990s) to Jérôme Kerviel (who cost French bank Société Générale $7.9 billion in a trading scheme not uncovered until 2007), you'll find a bank employee who had hoped to make a big profit for his bank and a big bonus for himself by taking a big risk, they point out. Instead, the rogue lost control of his trading positions and covered them up, often aided either by colleagues who hoped to protect themselves or by a lack of internal controls at the bank in question.

The controversy surrounding Wall Street investment research is just as dramatic as any rogue trading scheme and shows how compensation policies that offered rich rewards to employees for inappropriate behavior easily became an accepted part of Wall Street. Research analysts working for investment banks knew from the 1980s onward that their output—the analysis of various stocks, bonds, or investment strategies—was valuable to their employers only insofar as their recommendations generated either trading fees or investment banking revenues. A sell rating on a stock could be a career-limiting move for an ambitious analyst if it led to the company's management steering all their business to another firm.

As trading margins shrank, the pressure grew for analysts to help bankers win lucrative underwriting or merger advisory deals. And the analysts seemed eager to play along, realizing that since their

recommendations no longer helped the firm make trading profits, they needed to find an alternative way to demonstrate their value. Richard Braddock, CEO of Priceline.com, publicly declared that his firm picked Morgan Stanley to underwrite its 1999 IPO because of Mary Meeker, the firm's influential Internet and technology analyst. Meeker obligingly slapped a buy rating on Priceline.com and kept it there even as the firm lost 97 percent of its value over the next three years. At Merrill Lynch, Henry Blodget didn't downgrade a stock that he privately acknowledged to be a "piece of junk" until after the company in question had completed an acquisition on which Merrill earned advisory fees. At the end of 2000, Blodget sent an e-mail to his bosses at Merrill trumpeting his role in earning some $115 million in banking fees that year; he was rewarded with a big boost in his bonus, earning a total of $5 million.

That e-mail, along with thousands of others, were accumulated and studied by then New York attorney general Eliot Spitzer and his staff during their probe of the investment analysis business in 2001 and 2002, revealing a pattern of questionable judgment on the part of the analysts and their bosses. Perhaps the most dramatic example was the case of Jack Grubman, the star telecommunications analyst at Salomon Smith Barney (a division of what is today known as Citigroup). Grubman earned as much as $20 million a year in salary and bonus and helped his firm pocket at least $1 billion in fees arranging mergers or underwriting stock and bond issues for the companies he followed. But a CEO who couldn't generate lucrative deal fees for Salomon Smith Barney found it hard to get Grubman's attention, much less communicate the company's story to potential investors, although that, theoretically, was the heart of Grubman's job. "I tried to go to Jack and say we're the best of our peers and we're solvent, but I couldn't get in his office," Howard Jonas, chairman of IDT Corporation, told a New York Times reporter at the time the research scandal finally surfaced. "If you had big merger-and-acquisition opportunities, then you had a chance."[16]

A host of the companies that Grubman did pay attention to and give buy ratings to—including Global Crossing, McLeod USA, and, famously, WorldCom—ended by filing for bankruptcy protection.

(Until Lehman Brothers filed for bankruptcy six years later, WorldCom would remain the largest U.S. bankruptcy in history, involving $41 billion in debt and $107 billion in assets.) Grubman, along with other Salomon Smith Barney bankers, had advised WorldCom CEO Bernie Ebbers—now serving a twenty-five-year prison sentence for fraud and conspiracy—on dozens of deals, reaping fees for the investment bank. He continued to recommend the stock to investors right up until days before the company reported a $3.8 billion accounting error. Those on Wall Street may have been blasé about Grubman's ongoing bullishness when it came to telecom stocks—they knew that his firm wouldn't have stood a chance of winning the lucrative banking mandates had he cooled off—but even they blinked in astonishment at Spitzer's ultimate disclosure: a series of e-mails demonstrating a link between a sudden about-face on AT&T's stock (just in time for Salomon Smith Barney to win a top spot in the underwriting syndicate for stock in the wireless phone division, about to be spun off as a separate business) and his own personal financial interest. Specifically, Grubman agreed to raise his lukewarm rating on AT&T to a buy in exchange for help getting his toddler twins into the top-tier preschool at the 92nd Street Y—that help, it turned out, involved a $1 million donation from his firm.

Nearly everyone was happy. The toddlers were admitted to preschool, the Y got its donation, AT&T got its buy recommendation, and Salomon Smith Barney won a place alongside Goldman and Merrill as a lead underwriter for the AT&T wireless transaction, and thus a share of the fees that would help boost its status in the year-end league table rankings of each investment bank's market share.

Grubman and other exorbitantly well-paid Wall Streeters who have run afoul of specific securities laws, such as Mike Milken, will never work on Wall Street again. But they still got to keep the majority of their compensation for the years they spent there, and can, if they choose, parlay their experience into other jobs in the corporate world.

When Dow Kim left Merrill Lynch in early 2007, it was to set up

his own hedge fund. Normally, that would have been simple; even raising $3.5 billion in assets would have been relatively straightforward had Kim opted to leave midway through 2006 and waived his massive bonus. But his departure came just a few months too late; by the time he began trying to raise money, the problems with the products he had constructed for investors and that now were stuck on Merrill's balance sheet were apparent. Merrill itself, which had promised to back Kim's fund at the time of his departure, quickly reversed that pledge only months later. As of mid-2010, Kim hadn't raised enough from outside investors to formally announce the formation of his fund or begin deploying capital. On the other hand, he hasn't had to sacrifice any of the profits he made by structuring subprime CDOs, except for the value of any stock in Merrill Lynch that he still owned. (Kim was an active seller of Merrill Lynch stock in the year or two before his departure as his compensation levels climbed, according to insider-trading filings with the SEC.)

Efforts at Reform?

Several Wall Street firms began to tweak their compensation packages in late 2008 in response to the public outrage, introducing the concept of the clawback to investment banking pay packages. The first and most obvious step was for CEOs and other top executives to waive their bonuses for the year, and one by one, the announcements appeared. In some cases, those announcements were accompanied or rapidly followed by new pay policies, such as John Mack's proclamation at Morgan Stanley that in the future compensation would be tied to "multi-year performance and each employee's contribution to the Firm's sustainable profitability."

The ten-page brochure published by Morgan Stanley the following spring spelled out the basic tenets of this new approach to pay, including a commitment that 75 percent of compensation would be in the form of stock and that those stock awards to senior executives would be "at risk" for three years and would depend on

the firm continuing to earn a solid return on equity, generate profits for shareholders, and perform well compared to its peers. Moreover, an employee who "engages in certain conduct detrimental to the Company or one of its businesses—causing, for example, the need for a restatement of results, a significant financial loss or other reputational harm"—up to three years after the compensation is first awarded could have any bonuses clawed back by the firm.

Before 2009 was over, Goldman, embroiled in a public relations nightmare that had a lot to do with plans to pay out what might be record bonuses to its own team, announced something roughly similar. Goldman's top managers wouldn't get a penny of cash in their bonus checks, only stock. Moreover, those shares would remain "at risk" for five years, longer than those issued by Morgan Stanley as bonus payments. Other firms devised even more creative new policies. At Credit Suisse, illiquid assets such as leveraged loans and commercial mortgage-backed securities were placed into a $5 billion fund, shares of which were then awarded to executives as part of their bonus. The fund, set up in January, had already gained 17 percent by August 2009, Credit Suisse told its banking team. (The bank's stock, however, had soared 86 percent on the Swiss stock market in the same period.)

To a large degree, these initiatives recognize and respond to the degree of public outrage at Wall Street's lavish paydays of the kind displayed during congressional hearings when Representative Henry Waxman displayed a chart showing the growth in the pay packages awarded to Lehman Brothers CEO Dick Fuld. Fuld, sitting at the witness table, quibbled with Waxman's calculation that he had earned $484 million between 2000 and the firm's collapse in 2008, arguing that it was closer to $250 million, mostly in Lehman stock. "Is that fair?" Waxman demanded (largely rhetorically) of Fuld. While getting rich, Fuld and his colleagues "were steering Lehman Brothers and our economy towards a precipice." Overblown and hyperbolic statements on the part of other representatives and senators—many of whom had been quite happy to accept donations from Wall Street during its glory days—followed thick and fast.

Proposals for salary caps at firms that had accepted bailout money that they hadn't been able to repay were adopted; regulators and legislators were kept abreast of all bonus payments.

To some on Wall Street, the actions and rhetoric emanating from Washington were entirely logical. "I say this as a citizen: I think that what is going on is fair," argued Leon Cooperman, the hedge fund executive and former Goldman Sachs partner in the spring of 2009. "If business looks to government to moderate and control the downside risk, then the government has the right to control and moderate the reward. So we now need to get used to living in a world where that kind of stuff will happen and where government is going to be more interventionist." To others, it was an overreaction. "I grew up without much money, and my goal in being on Wall Street was to make $15 million or so over a number of years and then leave," says Casson frankly. "If anyone had tried to put a lid on how much I could earn in exchange for all my work, I would have looked for somewhere where my earnings weren't limited."

Most of the compensation reform schemes that were proposed or announced overlook the fact that past efforts to rein in greed have had all kinds of unintended consequences. After a Chinese wall was created between investment banking and research, as part of the reforms that followed Spitzer's investigation and the Grubman scandal, bankers no longer had a voice in which companies analysts covered or even which analysts were hired. Not surprisingly they balked at subsidizing the research division. Analysts' compensation was cut in half; many fled to hedge funds.[17] Those reforms, while theoretically creating less-biased research, didn't result in the creation of better quality research, at least not in a way that was easily accessible to the general public. "Come on, Mr. Obama, how are you going to attract anyone of the right caliber who wants the headache of running these firms, if you put these salary curbs in place?" wonders Guernsey, a private banker who has worked with many of Wall Street's top deal makers. "I have never overpaid for someone who is a top performer. Pay is how those top performers are recognized, traditionally."

Address the Cause, Not the Symptoms

The biggest problem with the various compensation reform initiatives is that they tackle the surface issues, not the root causes of the problem. Salary caps, for instance, are likely to be effective only in driving the most skilled Wall Street veterans out of those parts of the financial markets that are now being most rigorously monitored by lawmakers and regulators and into overseas institutions or other segments of Wall Street over which the government has little control. Those hedge funds that have ridden out the storm so far, for instance, continue to reward their employees as lavishly as ever. In the spring of 2008, Fortress Investment Group gave thirty-eight-year-old Adam Levinson $300 million in stock in the publicly traded hedge fund to persuade the star trader to stick around, despite the fact that the massive stock grant diluted the value of the holdings of other, public investors.[18]

True, in some cases investors have succeeded in pushing back management fees from 2 percent of assets to a more modest 1 percent and "persuading" managers to accept a smaller chunk of profits than the traditional 20 percent or 30 percent. In London, the three top executives at GLG Partners voluntarily cut their own salaries to $1 each, although they remain investors in their own funds and will continue to collect a share of any profits. One of the top hedge fund groups, Renaissance Technologies, is waiving its 1 percent fee on a newer fund that has performed poorly, people familiar with the industry say. Another large hedge fund group plans to collect its "incentive" fee at the end of three years on the net result of that three-year performance, rather than at the end of each year on what the fund had earned that year, says Patrick Adelsbach, a principal at the hedge fund research and advisory firm Aksia LLC. That is a big departure from the classic hedge fund compensation model that rewarded its managers at the end of each year for what had happened in the previous twelve months, which saw managers transform paper profits into cash fees thanks to the

wonders of mark-to-market accounting. “Marking,” or putting a market value on a hedge fund portfolio on December 31 of each year, gives hedge fund investors an idea of how their managers are performing. But the manager collects 20 percent or more of any gains in the value of that portfolio as a performance reward, regardless of whether or not that increase in value proves lasting.

Even when a risky transaction in that hedge fund portfolio later went sour, there was no way to claw back what had already been paid out in fees. All that investors could do was limit future manager paydays until the fund had recouped those losses. “A lot of managers found a way around that, too,” says a grim-faced Cooperman. “A lot of them, rather than working to make that money back, just say, ‘I quit,’ and hand the capital back to investors. If you tell me as an investor that you’re going to work for nothing and then when you do have losses just quit on me, that’s just not right.” Cooperman takes an even dimmer view of the increasingly popular strategy of shutting down one money-losing hedge fund partnership, only for its manager to reopen for business under a new name in less than a year.

If salary caps succeed only in driving the most talented bankers to parts of the market that government edicts don’t reach, they won’t get to the heart of the problem. Nor will policies that end up discouraging bankers and traders from taking any kind of risk whatsoever by making it too risky from a career and compensation standpoint. And while clawbacks are at least a step in the right direction, it’s a retroactive approach to solving the compensation conundrum. Of course it would be wonderful to be able to recoup past bonuses paid to people whose poor decisions and lack of attention to the risk associated with what they were doing end up bringing the financial system to its knees. (After all, murderers can’t collect life insurance premiums or otherwise inherit anything from their victims.) But it would be better still if the bright minds on Wall Street and in Washington could devise a compensation system that rewarded the denizens of Wall Street for avoiding such catastrophes in the first place.

Part of doing so boils down to defining more clearly who their

clients are. Ever since investment banks began going public, they have emphasized the degree to which their interests are aligned with those of their investors by pointing out the large stock holdings of their senior executives and the degree to which bonuses are paid out in stock. Having at least some "skin in the game" is seen as the goal, as Peter Blanton, a veteran banker, recalls from his days at Credit Suisse. "When the merchant banking team put together a deal, the folks that blessed it had to put some of their own personal capital into it as well as putting their names on the due diligence. It was a policy. There was a sense that without having skin in the game, we were just agents, without a long-term stake in the outcome." That attitude wasn't confined to the deals the bank did, but applied to their governance policies more generally. Gary Cohn, president of Goldman Sachs, told the Wall Street Journal in a 2009 interview that in his opinion, paying employees in Goldman Sachs stock is the "ultimate clawback." "When I got paid three years ago in $240 stock and it was trading [at] $54 or $53 … it certainly felt like a clawback to me," Cohn insisted. "We have always had … the ability to withhold stock or take it away for anything … done illegally [or] immorally."[19]

But if a heavy reliance on stock ownership was the foundation of a healthy compensation policy, then why did Bear Stearns and Lehman Brothers collapse? In both firms, from the CEO's suite down to the most junior bankers, ownership of the company's stock was encouraged and viewed by all as the best way to build wealth. And yet at both firms, groups of traders and investors were taking the same kind of outsized and risky bets as Dow Kim, who also collected more than half of his salary in the form of stock in Merrill Lynch.

By the time that bankers across Wall Street received their record pay packages at the end of 2006, interest rates had been climbing for nearly two years and the rate of economic growth had begun to slow amidst concerns about sky-high energy prices. The subprime lending cloud had begun to take shape overhead. And yet Wall Street, in the early months of 2007, was cranking out more mortgage-backed securities in the form of highly structured CDOs,

not fewer. And those CDOs were packed full of securities that carried more risk, not less. "To all intents and purposes, whether you got paid in cash or stock, the principle remained the same," says one former senior banker. "You were earning bonuses for maximizing fees, and the higher the fee income, the higher revenues and profits rose, and the better the ROE looked compared to your rivals, and the better the stock price did. It's all the same thing: pay was tied to profits." And at the end of 2007, the compensation on Wall Street hadn't fallen nearly as fast as some of the investment banks' stock prices. It's a cliché on Wall Street to say that financial markets are all about greed and fear; compensation, however, had become a matter of fearless greed in the mental calculus of at least a significant minority of traders and bankers eager for another record bonus day.

As long as compensation remains tied to competitive metrics—how much Bank A's return on equity exceeded Bank B's, or whether Bank B's share price grew more rapidly than that of Bank C—it won't matter whether an employee's bonus is 50 percent or 75 percent in stock. "One of the problems is that people lost sight of who their customers are, because there were so many of them, and instead focused only on delivering what their shareholders demanded of them," says a former senior banker who has now left the industry. "But do shareholders always know best? Is a rising stock price always the answer to every question?"

An asymmetrical compensation scheme that lavishly rewards excessive risk taking but fails to effectively punish failure is toxic in any environment, but when it isn't balanced by some broader consideration—the risks to the company, to investors, and to the financial system's health—then it becomes even more lethal. What happens, for instance, when a banker or trader is rewarded for his or her success in passing on a risky investment to a customer? Unless the problem is systemic—spread across Wall Street as a whole—the odds of such a problem wreaking long-term havoc on an investment bank's stock price are low. And if that banker or trader is otherwise a star, generating lots of fees from risky products of which only a few blow up (even though many others fare far less

well than the banker or salesman had promised), the odds of that individual facing a clawback—especially in a more normal Wall Street environment—are slim. After all, only a minority of mergers and acquisitions end up being successful, generating long-term value for shareholders of the companies doing the deals, and yet the bankers who propose, structure, and help to execute these transactions are rarely held up to scorn or asked to return their fees.

One of the most novel proposals for revising Wall Street compensation revolves around an attempt to bring back the spirit, if not the reality, of the era of partnerships when, as Lehman alumnus Peter Solomon recalled, the partners of a big investment bank sat around in one large room, literally or figuratively peering over each other's shoulders to ensure that their peers weren't taking too many risks. It may not be possible or even desirable to transform today's publicly traded financial institutions back into private partnerships.

But there may be creative alternatives. In a paper written for a conference held at the University of Seattle Law School, two law professors from the University of Minnesota put forth the proposal that any banker earning more than $3 million a year should be required to sign a joint venture agreement with their employer. "That would make them personally liable for some of the bank's debts," Claire Hill and Richard Painter conclude in the paper—and hopefully instill in them a greater awareness of the consequences of their risk taking. The duo point out that reckless risk taking is a Wall Street tradition. "Michael Lewis's description in his 1989 book of the term used for a star trader—a 'Big Swinging Dick'—reflected … an ethos in which investment bankers engaged in risky conduct and were no longer personally responsible for their actions."[20] Sure enough, a rogue trading scandal followed shortly after Lewis's book was published. Despite a boost from Warren Buffett, Salomon Brothers' brand name was damaged.

The two law professors point out that most of the existing proposals already out there—whether the prospect of vanishing bonuses or tying pay to the performance of not just the banks but also the debt securities that it sells to its clients—don't go far

enough. By and large these still involve "no risk of loss for bankers—only forgone gains." What is needed, they argue, is a proposal that is based on a different perception of banking as a "type of socially useful yet potentially 'ultrahazardous' activity that should involve … some measure of strict personal liability.[21] The limited partnership proposal is just part of their suggested reforms, which also include the proposal that bankers can shield only $1 million of their annual compensation from creditors in the event of their firm going bankrupt—the rest would be "assessable." That means that if a banker gets a $3 million stock bonus and his firm later goes bankrupt, $2 million of that stock—valued at the time it was granted—would be assessable, meaning the banker would have to pay its full market value at the time of issuance, or $2 million, to the firm's creditors.

Another proposed solution involves an approach that the Credit Suisse initiative hints at—putting Wall Street firms on the same side of the table with all their clients, not simply their shareholders or those that pay them fees. "If you're going to make a loan, or package some mortgage-backed securities and sell them, shouldn't your rewards be tied to the long-term success of the securities that you put your company's name on and sell to clients?" suggests private equity manager Tom McNamara. "You get paid when the things you sell pay off for the people that buy them, not when you sell them."

Paying out employee bonuses on the basis of deals that have only just been completed—long before it is possible to determine whether or not they were as rewarding for investors and other clients as they were lucrative for the institution selling or structuring them—is at the heart of the problem, in the eyes of many Wall Street veterans. Investment bankers shouldn't be richly rewarded unless their clients also make money, and certainly shouldn't be compensated when deals prove disastrous, whether for a client, the investment bank, or particularly for the financial system as a whole. One lawyer points to a structured product created within one part of an investment bank: the desk that created it earned a fee, but then another group of traders created a derivative structure atop the

original product that blew up, generating a big loss for another part of the same firm: "No one was tracking what happened across the various desks, so this product generated fees for people, even though it was utterly dysfunctional," the lawyer says.

McNamara, like many of the investors who have been consumers of the products that Wall Street generates, argues that investment banks should find some way to tie the success of the banker or trader not just to fee generation or corporate profits but to the success of their clients and the system's well-being. It's a view that is shared by Columbia University's Joseph Stiglitz. "Those who originate mortgages or other financial products should bear some of the consequences for failed products," he argued in his congressional testimony. Specifically, he recommended that the institutions originating mortgages be required to hang on to 20 percent of what they structure and sell. Stiglitz and others suggest that if that philosophy was extended to all of the transactions across Wall Street, with investment firms being required to retain a stake in every leveraged loan, junk bond transaction, or structured product that they sell, Wall Street would have a greater interest in maximizing not only the dollar value of the deals it does but also the quality of those transactions. In 2008, many of the products that caused meltdowns within Wall Street's investment banks were those that they had hoped to sell on to other investors but which ended up stuck on their balance sheets with no buyers in sight. "Isn't it ironic?" muses BlackRock's Rob Kapito. "These were the same securities that they wanted to sell to us, the buy-side institutions. If they'd succeeded, everyone would be talking about how well they'd done and how successful they had been." And the buy-side institutions and their own investors—401(k) plan participants, pension funds, individuals—would have faced even larger losses.

Questions of Value

Wall Street's core function may be that of a utility, but it is an unusual sort of utility. Rather than transmitting clean water or

reliable electricity supplies, it redistributes money throughout the financial system—and money is a far more exciting commodity than water or electricity. If you're running a power-generating station, it's easy to accept that what has value is the company you work for, rather than the commodity you are transferring from point A to point B. Certainly, if your bosses offered to pay you in kilowatt-hours, odds are that you would decline politely. But Wall Street transmits money, and a bit of every dollar that flows through the financial grid sticks to different players—the investment banks, trading firms, brokers, money managers, et cetera—in the shape of fees. Given that money is the one commodity that can be readily exchanged for any other tangible good someone might want, from food and shelter to a pickled shark by Damien Hirst or a trophy apartment on Park Avenue, it's hardly surprising that for those who live on Wall Street, life revolves around not just transferring money but finding ways to scoop up a bit more of the stuff for themselves.

Greed is an emotion as old as time, and it's asking too much of human beings to expect that those on Wall Street should take as detached a view of the commodity that they see pass through their hands as the manager of a power-generating station takes of kilowatt-hours. The Archbishop of Canterbury, the spiritual leader of millions of members of the Anglican Communion, suggested that investment banking bonuses should be capped, and called on their recipients to repent, arguing that "people are somehow getting away with a culture in which the connection between the worth of what you do and the reward you get [is] obscure."[22] But turning bankers into individuals who look down on money may be not only impossible but undesirable—after all, the money grid's job revolves around how to make the flow of capital more efficient and profitable for all concerned. The key word is all—while the bankers can't corner those profits, they also shouldn't be totally disinterested. Perhaps the appropriate strategy is to bring financial professionals to think of their jobs in the same way that lawyers view the law, or doctors the profession of medicine. Those groups certainly hope to earn large sums as a reward for years of education and training, but they recognize and acknowledge that their self-

interest goes hand in hand with a higher public and social interest, one that is explicitly acknowledged in medicine's Hippocratic oath and its cornerstone, the pledge to "do no harm." Placing one's own financial interests ahead of the interests of a patient or client can get a lawyer disbarred or force a doctor to relinquish her medical license.

The solution isn't to take a hammer to the current model, as defective as it may be, by imposing salary caps or punitive tax regimes. Rather, if Wall Street is to reach a point where its practitioners abide by their own version of a Hippocratic oath, what's needed is a longer-term strategy to tie compensation more closely not only to returns—whether short-term or long-term—but also to success in generating risk-adjusted returns and success in bolstering the health of the financial system as a whole. A first step in that direction is to be sure that even if Wall Street's firms pay out record sums in bonuses in the future (bonuses amounted to $20.3 billion of the financial industry's estimated 2009 profits of $55 billion, the New York State Comptroller's office announced), Wall Street compensation committees are taking risk as well as return into the equation when designing policies and fixing annual bonus levels. Of course, that assumes that those boards—and Wall Street—have a firm handle on what risk really is and how best to measure and control it.

CHAPTER 6

The Most Terrifying Four-Letter Word Imaginable

There are known unknowns. That is to say, there are things that we know we don't know. But there are also unknown unknowns. There are things we do not know we don't know."

When then Defense Secretary Donald Rumsfeld delivered that cryptic pronouncement at a February 2002 press briefing, he was commenting on the instability in Afghanistan, not Wall Street. And yet within a few years, the phrase "unknown unknowns" had become one of the most popular ways to summarize all that had gone wrong in the investment banking world. Somehow it was all the fault of the "unknown unknowns": Wall Street CEOs, individually and collectively, had misperceived, misunderstood, and mismanaged the risks associated with their business and the financial markets because of factors that no one could have anticipated, much less avoided. Yes, these apologists agreed, Wall Street had failed the ultimate risk management test, but that was due not to greed or arrogance but just to the extreme nature of the risks themselves. No one on Wall Street, surely, could have imagined and planned for the sequence of events that followed the endless and constantly escalating quest for fees, they argue. Certainly, that's how Lloyd Blankfein characterized events, in a verbal sparring match with FCIC chair Phil Angelides. But when he defined them as being akin to a hurricane in their ability to be predicted and controlled, an exasperated Angelides (himself the former head of a large California pension plan) shot back, pointing out that while hurricanes were defined as "acts of God," the financial crisis was the result of actions and inaction by human beings. That's convincing, but it raises one more question. Is Wall

Street's conviction that they couldn't have prevented what happened to be blamed on self-deception, wishful thinking, or blindness?

In Chuck Bralver's eyes, it comes closest to being the latter. The very idea of flawless risk management makes him laugh out loud—in his opinion, this would require an infallible crystal ball. Still, he remarks, Wall Street appears to be oblivious to the ways that the changing nature of its business created new kinds of risk. Bralver, a former senior banker with Oliver, Wyman & Co., now oversees the Center for Emerging Market Enterprises at the Fletcher School, Tufts University's graduate school of international affairs. In both of those roles he has spent a lot of time thinking about the nature of risk and the discipline of managing risk. "True, each separate event that led to the crisis, or that happened as a result of it, had an extremely low probability of ever occurring at all," Bralver says. "Then they all happened—and they all happened simultaneously."

But that doesn't give Wall Street a get-out-of-jail-free card. Even if bankers can't be blamed for their failure to predict this perfect storm, they still could have developed robust risk management policies to protect their institutions and the financial system from the "unknown unknowns," Bralver argues. One of the justifications for the increasingly lavish pay packages awarded to Wall Street executives was the increased complexity and scale of the businesses they were running. "It's not an accident that this happened after the changes that had transformed Wall Street [into a place] dominated by very, very large institutions that were no longer owned exclusively by the same people making the decisions about what risks to take," Bralver says. "It's possible that some of these organizations had become too large and complex for the kinds of risks they were taking, or that the risk management processes hadn't kept pace with the risk."

But why not? Describing the market cataclysm as a "perfect storm" is a great sound bite and helps the folks on Wall Street convey both the nature and the magnitude of events for critics on Capitol Hill and Main Street alike. But surely the same giant leaps forward in computing power and financial wizardry that made

possible the creation of instruments such as a synthetic CDO-cubed structure or a credit default swap also made it feasible to ensure that those products were doing what they were supposed to and distributing risk more broadly throughout the financial system. At the very least, shouldn't it have been possible to gauge when these new products were being used in ways that increased the risk Wall Street was taking to dangerous levels? Or if the markets had become too fragmented, too complex, and too fast-moving to make that possible, then shouldn't someone somewhere have been prepared to step in and say, "Wait a minute—we can't accurately gauge the risks associated with what we're doing"? And then to ask the next logical question: If we can't grasp the nature of those risks, should we be courting them in the hope of earning returns?

LTCM and Systemic Risk

The events surrounding the collapse of Long-Term Capital Management (LTCM) in 1998 gave Wall Street an early warning of the perils associated with "unknown unknowns." No one at the beginning of 1998 had expected a series of unexpected and nearly simultaneous events culminating in the Russian government defaulting on its bond obligations; because no one considered such a string of events to be probable, no one seriously pondered what might happen to LTCM as a result of the bets it was making and the degree of leverage it was using if those events occurred. As it turned out, LTCM's losses were so gargantuan that they threatened not only the firm (that would have been only normal) but all of its counterparties—which included nearly every major investment bank in the United States—and the financial system itself. Many of those firms didn't realize the magnitude of the risks they had been running until it was far too late.

In the wake of the LTCM crisis, which should have delivered a salutary lesson about the dangers posed by excessive leverage and "contagion," Wall Street didn't take a step back from the daily hubbub to do a forensic audit of the risks to the financial system

that the hedge fund's problems had exposed. The immediate danger over, Wall Street returned to maximizing its fee revenue, profits, and bonuses and too often shrugged off the concerns of those who, like Lehman's Mike Gelband or New York University professor Nouriel Roubini (who began warning of the real estate bubble as early as 2004), saw a new "perfect storm" taking shape on the horizon. When it came to managing risk, it was the risk of losing fees or market share rather than the risk of a blowup that weighed on the minds of most bankers and traders. Worrying about risks that seemed remote was in no one's interest.

In early 2008, UBS produced a report chronicling a series of errors of omission and commission to explain to its shareholders how it managed to lose a record $18.7 billion in its subprime structured product businesses in the previous year. UBS management set the stage for the debacle by deciding to act on the advice provided by external consultants; the best way to catch up to and overtake its largest competitors in key business areas—notably Goldman Sachs—was by expanding its activities structuring and trading products based on subprime and adjustable-rate mortgages. What neither the consultants nor UBS management took into consideration were the extra risks associated with following those recommendations and how the bank might manage those risks.[1]

The report lays out in chilling detail the myriad opportunities UBS bankers at all levels had to gain insight into the looming credit crisis, all of which were overlooked or ignored. In one case, UBS created the position of senior risk manager in the bank's fixed-income division in 2006. Would that individual have been able to perceive the risks that were looming? Could he have convinced superiors to rein in their risk taking? Would the bank have acted quickly enough to avoid large losses? The questions are academic: as of the summer of 2007, the position remained vacant and the bank's managers behaved as if the risk management function didn't matter.

In a mid-2009 survey, Capital Market Risk Advisors, a New York risk management consultancy, found that only 70 percent of the investment banks, commercial banks, investment management

firms, and hedge funds polled had a chief risk officer. Of those chief risk officers, only 25 percent had a say on issues such as how much capital a group can risk, or other such specific rules and policies, but did not create firm-wide policy. More worrying still, the vast majority of those chief risk officers reported not to the company's board but to senior management, who have a vested interest in maximizing profits at all costs. The board, which should have access to as much crucial information as possible about risk taking and risk management, may be in a poor position to rein in excessive risk taking, since a third of survey respondents only allowed their top risk management officials to attend executive board meetings once a year, if at all.

No Adult Supervision

Even when risk management procedures are in place, Wall Street is littered with examples of bankers running roughshod over them. At UBS, for instance, bankers were supposed to seek approval for new CDO products up front. In practice they delayed doing so until their division had already purchased and warehoused many of the asset-backed securities that would be included in the new CDO. Saying no to a deal at that point was possible only in theory; the costs of unwinding those holdings made it unfeasible in practice.

Often UBS bankers didn't even know what assets lay beneath the subprime loans that they were eagerly repackaging into CDOs. Were they first or second mortgages? What was each borrower's credit score? That kind of due diligence was being conducted by some investors, such as BlackRock's Scott Amero, but not by the product vendors. Instead, UBS and others on Wall Street placed blind confidence in the ratings; after all, they reasoned, credit analysts at Moody's and Standard & Poor's wouldn't give a coveted triple-A rating to anything that didn't deserve it.

Crucially, nowhere within UBS did anyone try to understand the importance to the market of liquidity and what might happen to the bank if something caused that liquidity to evaporate. (They

didn't have to predict what might cause such an event; all they needed to do was simply consider the fact that it could happen.) Similarly, until UBS began writing down the value of the subprime securities on its books in the spring of 2007, senior managers simply relied on the assurances of the people running the business divisions that everything was hunky-dory.

Those rank-and-file bankers had their own incentives to downplay the risks associated with subprime asset-backed securitization and the booming CDO market, even as it became a bigger part of UBS's business. Basic risk management principles suggest that any booming business should automatically be given more scrutiny, especially as its revenues and profits become vital to the firm's financial health and even its solvency. But Wall Street's mix of incentives didn't reward that behavior; rather, bankers were rewarded for downplaying any risks, for being courageous and aggressive. That, CEOs such as Stan O'Neal and Richard Fuld were sure, was the only way they could ever succeed in catching up with Goldman Sachs and matching the latter's enviable return on equity.

On Wall Street, "success" was defined in terms of the rapidity and magnitude of the growth of the business for which an individual was responsible, rather than prudence. Indeed, as the UBS report makes clear, at some institutions there was an incentive to deliberately take on more risk and not to look too closely at the potential fallout; the riskier the mortgage loan they agreed to underwrite and repackage, the bigger the fees. The UBS team responsible for structuring CDOs could earn fees of perhaps 0.5 percent, or 50 cents for every $100 of value in the CDO, by buying only high-grade CDOs containing top-quality securities. Or they could earn at least double and perhaps triple that in exchange for structuring a mezzanine CDO containing higher-risk securities. It was a no-brainer: they pursued the riskier option, which offered the best short-term rewards for both themselves and their division.

Since UBS's compensation policy rewarded bankers and traders based on how much profit they generated, there was no incentive to look too closely at the source of that profit. Was employee A really smarter than employee B because he generated more profit? Was

he making more money because he was better at capturing alpha, returns that had nothing to do with what was going on in the broad markets? Were his returns due solely to the ultralow cost of capital? Was he jeopardizing the bank's health in order to enrich himself, taking risks that might pay off for him in the short term in the shape of a gargantuan bonus but that would hurt the institution over the long haul?

No one at UBS could begin to understand which employees were generating the best returns on a risk-adjusted basis. The data weren't there because all that mattered to those who had designed the reporting and compensation system was the bottom line. Thus UBS, like its peers on Wall Street, paid out hefty bonuses on the basis of earnings gains that proved ephemeral. The bank itself was oblivious to "the quality or sustainability of those earnings" until it was too late.[2]

At best, bankers and traders assumed that someone else higher up in the food chain was doing the worrying for them; that someone would come and tell them if they were taking unacceptable risks. On Wall Street, however, there was no "risk police" to rein them in. As in most of the business world, every business division tends to operate with a large degree of autonomy. Why would the head of mortgage origination check in with the head of fixed-income trading? Their overall objectives may be the same—to maximize revenue for their institution—but they go about it in different ways and they compete with each other for access to the firm's capital to accomplish that. Wall Streeters reason that this would be about as logical as the product manager for Colgate toothpaste making sure that someone selling Hill's Science Diet pet food or Ajax cleanser isn't creating problems for the company that employs them all, Colgate-Palmolive. "Look, we were all just doing our jobs, in our little silos," says buyout manager Jake Martin*. "It's hard to blame people for doing their job, or to suggest that they should have been doing more than their job—or even more so, doing someone else's job."

Unfortunately, the comparison between Wall Street and a consumer products company (or other nonfinancial business) isn't

that clear-cut. They weren't selling toothpaste or even breakfast cereal. At the end of the day, all the myriad parts of Wall Street still were engaged in operating the money grid and making sure that capital moved smoothly from point A to point B. That function may have accounted for a smaller part of the industry's revenues and profits with every year that passed, but Wall Street, however ruthlessly it might seek out profits for itself and however dispassionate its users could be in allocating capital only to those who would use it efficiently and provide a solid return on their investment, ultimately operated in the public interest.

Were the interests of clients and of the public as a whole best served by organizing a Wall Street firm by product line? Several veterans argue against that approach. "The various products are really just tools that somebody can deliver to their client," argues one former senior Wall Street executive. He believes that had Wall Street firms focused on the client and the client's needs as a way to maximize fees, instead of setting up a structure within which each product group battles to maximize its own revenues, the result would have been a healthier financial system. "A derivatives desk sells products that are great; they are tools, really powerful hammers," the executive explains. "But when a derivatives salesman or manager talks to a client, the solution they propose always involves the hammer that they happen to have available and want to sell. Let's use this hammer to pound in the nail, to pound on this screw, to pound on your computer when it's not working. As long as they can make a case that the hammer might be a solution and can keep selling hammers, they are rewarded." An investment bank that divided its business by type of client—hedge fund, private equity fund, pension fund, endowment, mutual fund manager—rather than by product wouldn't have ended up in the same pickle, he suggests.

Others on Wall Street—a majority—reject such revolutionary ideas. Instead, they take an odd sort of comfort in Wall Street's long history of booms and busts. That was Jamie Dimon's worldview, even after the hurricane had blown through Wall Street. In testifying to the FCIC, he sought to explain his view of what had happened

by relating a story involving his daughter, who had called him from school to ask him what a financial crisis was. When Dimon told her that it was a market event that occurred every few years, she then asked why everyone was making such a big deal about it. (This anecdote was one of the rare occasions when Dimon—who has emerged from the crisis with a reputation that has been burnished rather than stained—appeared to be afflicted with the same kind of tone deafness and foot-in-mouth disease that afflicts some of his peers.)

In every market cycle, traditionalists point out, investment banks take big risks and many end up making bad deals. Wall Street is a Darwinian place: only the very fittest individuals or firms survive. So no one is surprised when every so often one of those investment banks takes a step too far and goes belly-up. Even Drexel Burnham went from being the most profitable firm on Wall Street in 1986 to filing for bankruptcy in 1990. Sure, it's sad for the guys who work there, but the good ones, Wall Streeters reassure themselves, will find another job eventually. (Indeed, a number of Wall Street firms today still are full of Drexel veterans.)

So even as subprime-related losses mounted and investment banks scrambled to find emergency cash infusions from overseas to help fill the holes in their balance sheets that had suddenly appeared, Wall Street prepared for little more than another Drexel-like event, something that would be painful while it lasted but that could be contained without posing a systemic risk. When the Federal Reserve forced Bear Stearns into a shotgun wedding with JPMorgan Chase in March 2008, there were some thinly veiled sighs of relief in a few corners of Wall Street. This was the moment of capitulation, they reasoned; Bear Stearns would be the subprime meltdown's Drexel, the sacrificial victim of the latest round of Wall Street excess. The real estate market would bottom out; there might even be a recession. But, they reasoned, the rescue of Bear showed that the risks could be contained.

But the closer bankers were to having an overview of the system, the more anxious they became. It was increasingly clear that to the extent they had pondered the issue of risk at all, they had been

addressing the wrong set of risks. They hadn't factored into their sometimes perfunctory deliberations the degree to which the financial institutions had become intertwined, so that the collapse of one automatically became a problem for others who had agreed to be counterparties in myriad financial transactions with the now-defunct firm. As the long, hot summer of 2008 unfolded, it also became clear that they had underestimated liquidity risk. Investors were becoming cautious, fearful, and unwilling to buy; they saw values as too uncertain. When buyers weren't willing to buy, how could the owners of securities understand what they were really worth?

Within weeks, liquidity—the lifeblood of financial markets—had begun to drain away, a process that would culminate in the massive credit crunch that fall, after the collapse of Lehman and the $85 billion AIG bailout signaled just how great the market catastrophe was. It was a chain reaction, and one that revolved around the level of confidence Wall Street institutions had in each other. The first to suffer were the investment banks, which relied on short-term financing to keep afloat. First Bear Stearns and then Lehman Brothers discovered that their usual financiers in the commercial paper and the overnight repo financing market had begun to perceive that the quality of the assets put up in order to obtain that funding had declined.

Liquidity risk was one of the most contagious of all forms of risk, as soon became clear. When Lehman Brothers collapsed, the plunge in value of the company's commercial paper led to an old-fashioned run on one of the oldest money market funds in the United States. The Primary Fund, managed by the Reserve Management Co., had about 1.2 percent of its $63 billion in assets invested in Lehman's securities, or $796 million. Investors panicked about even that tiny level of exposure, and demanded that the fund return $20 billion of their capital. That was more than managers could provide quickly however rapidly they sold other, creditworthy securities to meet those redemption demands. The chaos spread: other money market funds boycotted the commercial paper market, unable to value securities in the midst of a liquidity

crunch. The money grid stopped working—in part because of Wall Street's failure to understand the nature of the risks it was running, and liquidity risk specifically.

Wall Street, it seemed, had disregarded the possible impact of a string of "unknown unknowns" on increasingly complex and fast-moving financial markets that were more reliant on leverage than ever before. "It was all about denial, and every day one more person would realize that they couldn't stay in denial any longer," says private equity manager Martin. Wall Street had spent too many years embracing returns and closing its eyes to risk; now it was more vulnerable to a "perfect storm," while at the same time less prepared to survive the havoc such a storm would bring. "Some of us knew that something nasty was inevitable; in a way, we were all waiting for our comeuppance, for our cavalier attitude to risk to come back and bite us on the ass," one senior Wall Street executive recalls of the summer of 2008. "We were waiting for the next shoe to fall."

Understanding—and Misunderstanding—Risk

Everyone thinks about risk and return every day, whether consciously or unconsciously. When you wake up in the morning, you face the decision to get out of bed and go to work. The return is pretty straightforward: you keep your job and earn a salary to pay your mortgage and cover the grocery bill. Sometimes you accept greater-than-usual risks because you see the reward as also being above average. How many men who normally wouldn't dream of speeding aren't tempted to do just that when they are driving their pregnant partner, now in labor, to the hospital?

What happens on Wall Street isn't all that different; it's just a bit more intense due to the fact that financial markets revolve very explicitly around the dual concept of risk and reward. An investment manager takes risks—buying stocks, bonds, or other securities—in hopes of earning a return for her clients; if those risks don't generate profits, it's because she has misjudged either the

investment's return potential or the risks associated with it. Similarly, every time a trader on a Wall Street bond desk takes a bullish or bearish position in Treasury notes ahead of the employment data released on the first Friday of every month, he is assessing how much he could earn if the data show that 300,000 new jobs have been created the previous month or how much he might lose if it shows that 150,000 jobs were lost. Different data will have different consequences for the value of his Treasury notes. A skilled trader needs to be able to judge the myriad risks associated with his conclusion about the data and the Treasury position he chooses to establish. If he gets it right, how much might he earn? If everybody else in the market agrees with his assessment of the risks and potential returns, it's like betting on the favorite in the Kentucky Derby: the return will be minimal unless the trader makes the bet riskier by borrowing the money—in other words, unless he can use a lot of leverage. Betting on an outside chance, in contrast, offers more upside potential but carries a lot more risk of a different kind.

One of the biggest problems with risk is that its real level and nature are clear only with hindsight. Consider two hypothetical money managers, both of whom buy Google stock at the time of its IPO and hold on to it for the next four years. Now assume that one of those managers invested 20 percent of the assets she managed in Google, while the other invested only 2 percent of her fund in Google stock. At the time of the investment, the first manager would be called reckless and foolhardy by her peers and probably also by some of her clients; few self-respecting professionals would choose to keep so many investment eggs in a single basket. But by the end of 2008, it is likely that manager's bet on Google, however risky it looked at the time, would have paid off. Now, let's suppose that she did something even riskier by investing the remaining 80 percent of the assets she managed in Treasury securities. The risk here is a different one; she's not running much market or credit risk, since Treasury bonds are among the safest investments around, but she risks dramatically underperforming her peers because the tradeoff for that low risk is a tiny annual interest payment. Of

course, what is seen to be risky behavior in one context may look prudent or benign in another, as Treasury bonds outperformed every other asset class, except cash, throughout 2008.

It's often hard to correctly identify or understand the risk that you are actually running. Wall Street veteran and risk analyst Leo Tilman points out that even as the fees investment banks earned from their traditional businesses slumped and Wall Street institutions turned to "active risk taking" to generate returns for their shareholders, they were lulled into a sense of false security about the level and nature of risk.[3] "When the environment that you're doing business in is very benign, the risk management models start telling you the level of risk is declining, so you feel comfortable taking on more risk," Tilman explains. Whenever investment banks alter their traditional business model in the pursuit of higher fees, higher returns on equity, and higher bonus packages, they automatically take on more risk, he says. The commoditization of traditional businesses—as discussed in chapter 3—forced Wall Street firms to focus on new kinds of business, most of which involved new kinds and often higher levels of risk, Tilman believes. "The paradigm of risk management never caught up with reality," he argues.

In Tilman's eyes, the CDO business, which produced so much of the carnage on Wall Street in 2007 and 2008, is prima facie evidence of the Street's misunderstanding and mismanagement of risk. To the likes of Merrill Lynch and UBS, buying up mortgage-backed securities and repackaging them into these new structured CDO products (the CDO would then be sliced up into tranches on the basis of different risk and return characteristics) was simply a new way to earn the same kind of fees they had always earned. It wasn't really a new business, they reasoned, especially in a low-interest-rate environment. They saw it as "a riskless fee business," Tilman says.

In the eyes of Wall Street, a business that generates a fee is inherently far less risky than one that requires a long-term investment of capital and where returns come in the form of profits following the sale of an asset some time in the future. So even as

the Wall Street firms committed more and more capital to the CDO business, they could tell themselves they were still acting as intermediaries between the mortgage originators and the ultimate investors. That gave them an artificial sense of security. Tilman argues that such behavior bordered on the delusional. "If you're gathering CDOs together in a warehouse and packaging them up, and the market suddenly freezes, well, that's a big risk," he says. "It doesn't matter that you would have eventually earned a fee from the transaction. If you believed it was a plain and straightforward transaction and if you didn't hedge the risk of keeping all those [mortgage-backed securities] on your balance sheet while you packaged the CDO, well, you didn't understand the risks you were really taking."

Tilman watched the debacle take shape and then unravel from positions at BlackRock and later as an investment strategist at Bear Stearns advising the firm's pension fund clients and other institutional investors. In his view, this pattern showed up across the whole array of Wall Street's most popular and most profitable new business lines. "Opening a proprietary trading desk, providing short-term financing for leveraged buyouts, serving hedge funds, starting an in-house hedge fund—none of this is as low-risk as people convinced themselves it was."

Of course, everyone on Wall Street knows that their business revolves around risk. But when you ask them about it, they'll tell you it's not about Wall Street taking risks, it's about Wall Street helping its clients offload what they consider to be unacceptable risks to another player. It's about risk transfer. The classic example of this is one of the most basic derivative securities, the swap: in its original form, this was a way for a company to exchange debt on which it had to pay a variable interest rate for fixed-rate debt, making its finance costs more predictable. Still, as big investment banks became more complex and placed more emphasis on using their capital to generate returns, they admitted it was time to hire in-house risk managers.

Ideally, Wall Street risk managers should play the role of circuit breakers. They should be able to force the bankers and traders at

the various investment banks and other institutions to pause to consider whether they really understand the risks they are about to run and whether the potential return seems worth it. Unfortunately for everyone, Wall Street's relationship with risk managers hasn't always been healthy or productive. Financial institutions have pushed risk management to the sidelines and overlooked it entirely just when they needed it the most: when the level of greed is rising to new heights.

The Least Popular Guys on the Street

Wall Street loathes a party pooper—the guy who arrives on the scene and shakes his head in solemn disapproval of the antics while everyone else is having fun. This most unpopular subspecies wants you to walk away from a deal that is going to generate hundreds of millions of dollars in fees, especially when it's going to cost you a zero on the end of your annual bonus check.

Risk managers on Wall Street are about as popular and welcome as a sensible spouse or cautious bank manager whispering words of reason to a Vegas gambler about to bet the ranch at blackjack. The last thing that a Wall Street banker wants is for that risk manager to acquire enough power internally to force him to listen and limit the risk he's taking. Bankers see risk as a way to make profits for themselves and the firm's shareholders; risk managers, meanwhile, want to be sure the institution survives long enough to book those profits. Not surprisingly, those interests often clash, and finding a compromise is hard because both have logic on their side. Play it too safe, and the bank won't make money; take too much risk, and the bank won't exist much longer.

On Wall Street, however, the political power is in the hands of those who want to take more and more risk, not those who advocate caution. That's because the bankers and traders who generate the heftiest profits over the longest time periods (and who also have the diplomatic skills to win the support of large numbers of other big revenue producers) are the people who rise to the

positions of power within investment banks and other financial institutions.

That's what happened at Goldman Sachs, which once had maintained a balance of power between trading and investment banking within its leadership. (One odd couple was Bob Rubin, a veteran trader, and Stephen Friedman, known for building the firm's merger advisory business, who were co-chairmen of Goldman in the 1990s.) But by the new millennium, the leadership was coming under the control of the traders, such as Blankfein and Gary Cohn, the firm's president, both of whom had begun their careers at J. Aron, the commodities and futures trading business Goldman had purchased. Their trading operations were driving profits, and they were comfortable with risk; still, their priority was clearly on maximizing returns. That's how any banker gets to a position of power and influence in the first place, and it's what they need to keep doing in order to keep shareholders happy and retain their jobs. Anyone who wonders if it might be wiser not to push the risk envelope just has to recall the fate of Phil Purcell or Mike Gelband.

Jaidev Iyer learned the lesson about the balance of power between risk managers and reward seekers firsthand during the twenty-eight years he spent at Citigroup. From the Global Association of Risk Professionals (GARP) offices in New Jersey, Iyer has a panoramic view across the Hudson River to the gleaming office towers of Manhattan, including the skyscraper where he toiled as head of operational risk for Citigroup. He has an equally panoramic view of what went wrong on Wall Street. "Everyone is to blame," he says flatly. "No one is exempt, and I include risk managers in that." But risk managers carry a different burden and thus a different kind of blame, he argues. "Their primary failure was a failure to understand or communicate the risks."

Think of the old legend of the turtle and the scorpion. The scorpion, who needs to get across the river but can't swim, asks the turtle to carry him. The turtle initially scoffs at the idea. "Are you mad?" he demands. "You'll sting me while I'm swimming and I'll drown." The scorpion points out that if he did, he'd drown, too. "Where's the logic in that?" he inquires. The turtle, convinced, tells

the scorpion to hop aboard, and starts swimming. Halfway across, the scorpion stings the turtle. As they sink to the bottom of the river, the turtle turns resignedly to the scorpion and asks, "Why did you do it? You said there'd be no logic in you stinging me." "It has nothing to do with logic," the scorpion answers sadly. "It's just my character."

On Wall Street, the turtle is the risk manager who knows full well that the nature of the bankers and traders is to take as much risk as they can in pursuit of profits. Failing to find an effective way to communicate the potentially toxic consequences of loading up the bank's balance sheet with subprime loans is the equivalent of the turtle agreeing to ferry the scorpion across the river. The risk manager becomes complicit, indirectly, in the subsequent losses and write-downs.

Iyer says managing risk on Wall Street is more easily said than done, since risk managers don't generate profits for their firms and can even recommend actions that would curb short-term gains. "The guy who is always forecasting Armageddon is never going to be the guy anyone wants to listen to; if you listened to him all the time, you'd never do anything," Iyer says. "You have to do that without becoming a wet blanket."

Still, Iyer admits that during his years at Citigroup he found it difficult to always practice what he preaches. At a 2007 meeting of the bank's risk committee, he annoyed Tom Maheras, the powerful co-head of investment banking, by suggesting that the latter hadn't set aside enough capital to provide for some operational risks Iyer had identified. Maheras, a bond expert and a veteran of Salomon Brothers and its high-risk, high-return culture, was an aggressive banker who had risen to the top ranks of Citigroup. Transforming the bank into the dominant global fixed-income trader and propelling it toward the top of the underwriting league tables meant taking on more risk, he was convinced. Sure enough, Citigroup's average value at risk (VaR, pronounced as one word to rhyme with car), a measure of how much the bank could lose in a single day if its strategies fell apart or the markets turned sour, soared from $63 million in 2001 to $105 million by 2005.

Perhaps Maheras's track record made him comfortable with risk taking. Bankers who worked with him agree that to Maheras, risk equaled returns. Setting aside more capital to guard against future losses, as Iyer suggested was prudent, would crimp Maheras's style and potentially cap profits. Not surprisingly, Maheras was angry; Iyer's suggestion promptly died. More surprising, Iyer was told not to attend further risk committee meetings. Most surprising of all, it wasn't Maheras who had banned him but the bank's senior risk managers. "They wanted to keep Tommy happy," says Iyer with a shrug.

Others trying to alert top management at Citigroup to looming problems received even shorter shrift. Richard Bowen was named chief underwriter at Citigroup in early 2006—just as Wall Street approached the abyss. That promotion meant he was in charge of making sure that all the mortgages Citigroup's business divisions acquired for resale to government entities like Fannie Mae or other investors met the bank's quality standards. Within months, Bowen realized that nearly two-thirds of them didn't, according to the FCIC report. That meant that if they lost value, investors could demand that the bank repurchase them. Attempting to signal the danger to his superiors, including Bob Rubin, led only to expressions of concern; the only action was a renewed push to boost market share. "So we joined the other lemmings heading for the cliff," he said in an interview with FCIC staff.

Bowen's career also went off the cliff; after he began sounding the alarm, his bonus was slashed, he went from supervising 220 people t o overseeing only 2, and his performance evaluation was downgraded, the FCIC reported. He wasn't alone: across Wall Street, numerous other risk managers or business-unit heads who detected the risks their institutions were running and who tried to apply the brakes, were fired, sidelined, or stripped of any power. At Merrill Lynch, for instance, risk managers no longer occupied positions on the trading floor where they could watch what was occurring in "real time."

Maybe it shouldn't have been all that astonishing. However important the risk management function seemed to be to those

performing it—they knew their activities helped keep their institutions from incurring large losses or running afoul of regulators—risk management didn't generate profits. And profits are all-important on Wall Street, whose icons are bankers such as Maheras, Joe Perella (now out on his own again after leaving Morgan Stanley), or Jimmy Lee at JPMorgan Chase. This list would include some hedge fund managers and buyout investors. But ask the average investment banker the name of Wall Street's smartest risk manager and you'll likely get a blank stare in response. Even the most successful toil in anonymity.

The UBS forensic analysis of the causes of its massive losses confirms that risk managers had trouble getting their message across. In some cases, they had become too eager to please the more powerful bankers. The UBS report cites one example after another of occasions when managers at all levels silenced points of view that conflicted with their own. UBS bankers complained that the bureaucracy associated with risk management caused them delays in earning revenue from new businesses; their logical response was to find ways to bypass the risk management team or to co-opt them. When bankers explicitly requested more favorable treatment for pet projects, risk managers listened agreeably. In one case the report concluded that if the risk team had been more alert to their circuit-breaker role, such a request could have pushed the bank "to rethink the rationale for the business model as a whole."[4]

Some on Wall Street did listen to what their gut was telling them: that when things seem too good to be true, there is usually something amiss. Whether or not the increasingly popular quantitative risk models captured it, risk-conscious bankers and their analysts knew instinctively or had learned from experience that when it seemed as if nothing could go wrong, it was time to look around for the hidden iceberg ready to rip a hole in the side of the vessel. But to be able to ask the right questions and draw the right conclusions required not only common sense but also the willingness to be a contrarian, even in the absence of evidence that there was a real reason to be alarmed.

Asking Questions, Challenging Models

At Sandler O'Neill, a boutique investment bank catering to financial institutions, CEO Jimmy Dunne was aware that he had a few hundred million dollars' worth of trust-preferred securities (a kind of low-cost financing favored by financial companies) sitting on the firm's balance sheet in the spring of 2007. That was routine; Sandler O'Neill was warehousing the securities while awaiting the right time to repackage them and sell them to investors. But Sandler O'Neill's balance sheet was much smaller than those of firms such as Merrill Lynch, making Dunne nervous. He started investigating the firm's risk.

It all boiled down to just one question, which Dunne asked in the summer of 2007. He wanted to know how much collateral the firm had on its balance sheet in connection with the trust-preferred securities. Hearing the answer, and realizing that the figure was out of whack with the historic average, Dunne reacted instantly. "I told them to get out [of the positions in the trust-preferred securities], forget what the models said [about value], to just sell everything. I had to assume the worst-case scenario, for the sake of the firm."

Dunne had learned over the years that following closely in the footsteps of bigger Wall Street institutions wasn't necessarily prudent. More than a decade earlier, his closest friend and the head of investment banking at Sandler O'Neill, Chris Quackenbush, had pointed out that just because a firm is bigger doesn't mean its behavior or attitudes are worth emulating. They had both learned that lesson when Sandler O'Neill underwrote a new stock issue for a client alongside Salomon Brothers (now part of Citigroup). Quackenbush cautioned Dunne that the SEC rules required underwriters to stay out of trading activity in the stock for two days after the issue was priced and sold. The next morning, Dunne spotted Salomon's trading desk busily making a market in the stock and raking in fees. He stormed into Quackenbush's office, furious at losing potential profits to a rival firm. "I said, 'Look, pal, don't tell me they don't have lawyers and risk guys all over at Salomon.

Come on, we're losing money!' "

Quackenbush—one of the sixty-six Sandler O'Neill employees killed in the 2001 terrorist attack on the World Trade Center—stood up to Dunne. "He said he didn't give a hoot—only he didn't use the word hoot—about what another firm was doing," Dunne recalls. What mattered was that Sandler O'Neill should do the right thing and not take foolish risks. Dunne says those events taught him a lesson he would later recall as he watched Merrill Lynch, Citigroup, and others accumulate massive exposure to subprime CDOs. "The big guys may build the system that the rest of us have to live in, but we don't have to follow what they are doing blindly," he says today.

It would have been far harder for Citigroup to sell or hedge the $43 billion in subprime securities sitting on its balance sheet than it was for Sandler O'Neill to slash its much smaller exposure. But in the summer of 2007, Citigroup's CEO, Chuck Prince, didn't seem to be asking the same questions that Dunne was. Indeed, it wasn't until he convened a meeting in September to discuss the market meltdown that was already under way that Prince grasped the magnitude of the bank's exposure. His once-blissful ignorance would cost him his job before the year was over. At Merrill Lynch, Stan O'Neal had built a culture revolving around his dream of transforming the firm into the next Goldman Sachs; now he too was put out to pasture. (Nearly simultaneously, and perhaps not coincidentally, Merrill finally created and filled the position of chief risk officer.)

Wall Street investors were much more alert to subprime-related risks. They watched with concern as Wall Street's CDO creation machine churned out more and more of these structured products, each containing a higher proportion of subprime loans than its predecessor. But then, they were looking at the market from the perspective of an investor, and had long had concerns about the extent to which ultralow interest rates failed to reflect the real levels of risk. "The pricing became ridiculous," says Bill Kohli, a fixed-income manager at Putnam Investments in Boston. "The more risk you took, the better your performance was; [bond] yields got

so low that in order to generate the same returns you had a few years earlier, you had to take a lot more risk."

If Wall Street's investment banks and the mortgage companies who were providing them with their raw material didn't get the trade-off between risk and return, investors did. For them, buying CDOs was a long-term investment, in contrast to Merrill Lynch or Citigroup, which planned to pass the CDOs to someone else, along with their risk. To compete with their rivals, investment managers need to offer superior returns, but to keep their own investor base satisfied, those returns have to be steady and consistent. Taking too much risk raised the odds of losses, which would in turn cause fund investors to demand their money back.

By 2006, it seemed to Kohli and many of his peers that whichever way they turned, they saw only risk. Many bond managers recognized that yields being offered on corporate bonds were ridiculously low by historical standards; since bond prices and yields move in the opposite direction, for investors to make money by buying those bonds, the yields would have had to fall still more, an improbable scenario. Yield levels were so low that just pocketing a bond's income stream wasn't an attractive option, either. And anyway, how many of those securities might run into trouble if the economy stalled and borrowers struggled to make payments?

Another risk was that an increase in bond yields would send the bond's price, and therefore its value, plunging. Many still decided to hold their noses and buy higher-yielding products, reasoning that many of those structured CDOs had been assigned triple-A credit ratings by Moody's or Standard & Poor's. Somehow, a majority of them managed to overlook the odd fact that for every blue-chip U.S. company worthy of earning a triple-A rating from one of those credit rating agencies, there were thousands of structured products carrying the same seal of approval. Others began to balk as the products became increasingly complex or opaque, or valuations reached what they considered to be extreme levels. Some, including BlackRock's Scott Amero, did the due diligence into the loans that underpinned these securities and recoiled in horror at what they

found. Between the summer of 2006 and late 2007, the number of borrowers who defaulted on their new mortgages only months after signing on the dotted line doubled, as the FCIC reported. Some homeowners never even moved into their new abodes. "Buyers of CDOs are given a take-it-or-leave-it deal; the investor isn't at the table participating in the discussion of how to structure the CDO alongside the issuer and the guy from Moody's or S&P," says Ed Grebeck, CEO of Tempus Advisors, who teaches courses on structured finance at New York University. "For fixed-income managers, this was what was available—end of story." And fixed-income managers were encouraged to put their trust in those ratings; after all, the ratings told them whether a particular bond could be added to their portfolios.

Aware that the CDO vendors are in the business of boosting their own bottom line, some investors began focusing instead on relative risk. "There were blue-chip companies that were the subjects of leveraged buyouts, and many of those leveraged loans and bond issues, while a bit pricey sometimes, weren't flawed," says Amero. "They certainly suffered [in the midst of the credit crunch], but they [were] still securities that we believed [were] fundamentally good." He points to the loans sold in connection with the $26 billion buyout of First Data Corp. by KKR as an example (although the company, as of early 2010, was recorded as incurring a loss for KKR itself).

Some investors couldn't react to the risks they identified. A bond fund mutual fund manager, for instance, has to invest in the kinds of fixed-income securities that are deemed permissible by the terms of the fund. But while such rules left many mutual fund managers in a bind, hedge fund managers had far more freedom of action. While raising capital, a hedge fund manager spells out the broad strategies that he intends to employ to generate returns in an offering document—a "long/short" or "event-driven" strategy, for instance—but he usually leaves himself with a lot of room to maneuver. So when John Paulson began to grow alarmed by what he believed was a credit bubble, all he had to do was decide how to profit from the recklessness of others.

Paulson, a former investment banker, decided that the subprime mortgage market was the part of the credit bubble that seemed the most overextended. He began using derivatives to short subprime mortgage securities in April 2005. It was the culmination of months of thought, analysis, and planning; the bigger any subsequent decline, the larger the profits Paulson's fund would capture. "We thought [this position] was a terrific risk-return tradeoff where you can risk 1 percent and make 100 percent," Paulson said in July 2007. "The exuberance in the credit markets and the massive liquidity was severely mispricing these securities."[5] That turned out to be the understatement of the decade. Paulson's Advantage Plus Fund returned 158 percent to investors in 2007 and another 37.6 percent in 2008, a year in which the Standard & Poor's 500 index fell 36.9 percent. The Credit Opportunities Fund fared even better, returning 600 percent to investors. Paulson himself pocketed an estimated $3.7 billion as his share of those returns; by paying heed to hidden sources of risk, suddenly he had become simultaneously a billionaire and a household name.[6]

If Paulson, working outside the mainstream investment banking community and relying on public information, could spot what was going on and take action, why couldn't Wall Street itself? Only a handful of mavericks such as Paulson spotted the opportunity to be a contrarian; few bankers seemed to have any sense of the risks associated with their own behavior and/or felt the need to act. Some of these were at Goldman Sachs, whose chief financial officer, David Viniar, convened a meeting in December 2006 to discuss subprime-related risks. The participants (who included risk managers) agreed they would kick off the new year by establishing a short position, a strategy that paid off richly for the investment bank and certainly contributed to its survival. Later, Lloyd Blankfein would attribute Viniar's initiative to what he described as Goldman's greatest "risk protection"—giving as much status, prestige, and compensation to the risk managers seeking to control the investment bank's finances as it did to the bankers and traders.[7]

For the most part, however, Wall Street seemed content to pursue its own peculiar brand of magical thinking. In the parallel universe

as imagined by investment bankers, risk was minimal and readily managed, the supply of cheap credit was endless, and buyers were eager and plentiful. Wall Street's willingness to act as if reality was what they imagined it to be generated a toxic combination of blind faith in its own ability to manage risk and willful blindness to what should have served as warning signals. The result would be the effective demise of three of the five largest investment banks (Bear Stearns, Lehman Brothers, and Merrill Lynch, the last of which opted to be acquired by Bank of America) in little more than six months in 2008. It also brought about the near collapse of Wall Street itself.

Wall Street's Magical Thinking

Key to Wall Street's magical thinking was its reluctance to look risk straight in the eye. Of course, until the summer of 2007, there were few obvious signs that the bull market in credit would have such cataclysmic consequences. Those who persisted in voicing discomfort about the pace at which deals were being done, at the lofty valuations or at the degree of leverage, might be proven right in the long run, but for now would be laughed at and shunned, and perhaps even lose their jobs.

"Even to someone with a lot of expertise in risk management, it was hard for us to envisage while we were absolutely awash in liquidity that the biggest risk we faced was the sudden evaporation in market liquidity," says Leslie Rahl, founder of the risk consulting firm CMRA, whose "workouts" have included many of the derivatives debacles of the 1990s. What seems obvious now wasn't at the time, she adds. "It seemed illogical not to just keep doing what had worked." After all, until early 2007, there hadn't been a bank failure in nearly three years. Even when Pittsburgh's Metropolitan Savings Bank collapsed in February 2007, there was no reason for magical thinkers to view it as anything other than an anomaly; only three institutions were shuttered by the FDIC that vear. the same number as failed in 2003.[8] And 2003 had turned out

to be a pretty good year for financial markets, they reasoned.

When Wall Street worried that it might be missing the warning signs of an extreme event that could threaten the financial system as a whole, the issue of a credit market bubble and subprime lending rarely served as the focus of those debates. Instead, risk managers at firms such as Lehman Brothers in 2006 worried about the impact of another terrorist attack like those of September 11, 2001, or of an epidemic of avian flu on global financial markets.[9] In contrast, the ultraliquid credit markets seemed unlikely to be the center of a financial markets disaster rivaling the 1929 stock crash in magnitude and significance. In the absence of any bank collapses and in the presence of record low bond default rates, the calculus made sense. Maybe there was a credit bubble out there, but bubbles can exist for a long time without bursting. An investor or banker who takes to the sidelines at the first hint of trouble can lose a lot of money and forfeit his credibility, the late 1990s had demonstrated only too clearly. Former Fed chairman Alan Greenspan wryly reflected on the relevance of that period, noting that "underpriced risk—the hallmark of bubbles—can persist for years."[10] (It took three years from the date Greenspan warned of "irrational exuberance" for the dot-com bubble to finally burst.)

Wall Street, by and large, wasn't listening to its risk managers. It wasn't doing its best to detect warning signs. While most experienced risk management professionals agree that the very time a business is booming is exactly the time to start worrying more about what risks might be going unnoticed (from excess leverage to the presence of a rogue trader), Citigroup's David Bushnell instead admitted to the FCIC that, in general, his risk management team actually boosted risk limits for a growing business. One of his team, Ellen Duke, later acknowledged that she didn't worry as much as she should have about the CDO business, in large part because she believed that the way the products were structured would reduce rather than increase the amount of risk. She confessed to being "seduced by structuring."

Wall Street seemed to be relying exclusively on a handful of quantitative risk-management models to save the financial system

from disaster. The immense forward leaps in computing power that had made possible the creation of complex derivatives and other structured products had also made it possible for mathematical minds to devise ways to track and calculate different kinds of risk across a multitude of different business segments rapidly and efficiently. Computers also made it possible to simulate shocks to the system and watch how markets behaved. These models had a kind of entrancing elegance to them, and that helped produce an unwarranted degree of confidence in the numbers they generated. What users of these models forgot is that simply being able to generate a number and label it "risk" didn't mean that the model's assumptions were correct, that the number was useful or would remain useful in all market environments—especially because a growing proportion of the securities that could swing most violently and trigger the biggest losses for their holders weren't publicly traded, but "over the counter" derivatives. The spread of derivatives made risk management a more complicated task. If an investment bank had shares of Cisco and General Electric on its books, for instance, the impact of a market shock would be relatively straightforward to calculate; those stocks trade on an exchange and have a clear market value. But only a fraction of the world's financial instruments are that easily monitored. What would happen to a corporate bond? They don't trade as often, and dealers in those bonds make a market in them on an ad hoc basis when a potential buyer or seller requests price information. Who would be willing to be an intermediary in times of market stress? And at what price? Then there are the derivatives, which also aren't traded on an exchange (except for the plain-vanilla variants, such as options and futures contracts) and which often are highly customized products that don't have a logical buyer.

That's just the very tip of the iceberg. Today's investment banks are global: their risks can be related to the trading they do with a Kazakh oil and gas company, the loans they make to a Thai retailer, or a buyout they finance of a Mexican food processing company by a European conglomerate. Throw a stone in the waters of global markets today and the ripples will take a more unusual shape and

stretch far wider than they would have a decade ago. Hence the allure of the quantitative risk management model in the eyes of investment bankers.

The Value at Risk Conundrum

The best-known of these models is the famous (or infamous) value at risk (VaR) model. "Essentially, that was the solution devised to the problem of a CEO who walked onto the trading floor and wanted a simple answer to the question of how much risk the investment bank was running today," explains Jaidev Iyer of GARP. "With VaR, you could give him a single number—how many dollars the bank could lose today if things went wrong." VaR vaulted into prominence when an international group of banking regulators, the Basel Committee on Banking Supervision, explicitly endorsed it as a way to gauge how much capital a financial institution is putting on the line, and thus to calculate how much capital it should set aside to shield itself should those risks backfire.

The result was the Basel II accord, first published in 2004, which required financial institutions to incorporate risk into their balance sheet decisions. In quest of additional profits, financial institutions pushed hard for a tradeoff: if they could demonstrate that they had all kinds of risk management models like VaR, then regulators would give them a break by relaxing requirements on how much capital they had to possess to guard against big losses. The tradeoff was alluring to the bankers; regulators would later argue privately that they had always had reservations but capitulated under relentless pressure from the industry. The balance had shifted: regulators now would, de facto, be more dependent on the banks' own in-house evaluation of the magnitude and nature of the risks the latter were running, despite the fact that those financial institutions had every incentive to underestimate those risks.

After a lot of debate—it took five years to hammer out the basic principles, and implementation still wasn't complete when the crisis broke—the signatories (including central bankers and other

regulators from twenty different countries) finally agreed that banks, investment banks, and other financial institutions could rely on VaR as a way to gauge risk. The lower the VaR, the less capital an institution needed to set aside to shield the firm from risk. But at the end of the day, no one was happy. "Nobody believed in it and nobody used it, except in the annual report and to tell regulators what was going on," says one former regulator. "Everyone in the regulatory community knew there were failings with this process. But at the same time, it had been so hard to agree on this, and so controversial, that no one who worked on Basel ever wanted to reopen the topic for discussion again."

The biggest problem with VaR—and with any other effort to model risk—is that while Wall Street may concern itself with numbers, human behavior is just as important a determinant of what happens there. And human behavior is notoriously difficult to quantify. But as VaR increasingly demonstrated throughout the Wall Street crisis, numbers didn't tell the whole story.

To start with, VaR couldn't give anyone an accurate picture of how well risk was being managed. For instance, the VaR associated with Goldman Sachs's sales and trading business was $101 million in 2007, meaning that on any given day, that was how much it might lose with a defined degree of probability. Goldman was second only to Citigroup in the amount of risk, and it also earned more in revenues than any other financial institution from those trading activities—$27.5 billion in 2007, up 21 percent from the previous year. On the surface, Lehman looks less risky in absolute terms. Its VaR was $92 million, and its revenues from sales and trading were about half of those at Goldman. But VaR doesn't tell the whole story. It was Lehman, not Goldman, that experienced the biggest increase in VaR (it more than doubled, the highest rate of growth of any investment bank in 2007), while it increased only 37 percent at Goldman Sachs. Moreover, the size of Lehman's VaR relative to that of its trading revenue was higher than the same ratio at Goldman. Moreover, Goldman lost money on fewer trading days in 2007 than in 2006; the number of days on which Lehman's traders lost money jumped from five in 2006 to thirty-three in

2007. Goldman made more than $100 million on each of eighty-nine trading days; Lehman pulled off the same feat on only thirty-one days.[11] In other words, VaR alone gives a hopelessly inadequate view of the two organizations' ability to manage the level of risk that they were taking. "It didn't tell you anything at all about the caliber of assets on the balance sheet connected with those risks, or the skill of the bankers and traders," argues one veteran banker and risk manager.

It didn't help that some of Wall Street's more aggressive CEOs were prodding their traders to take more risk and, like Stan O'Neal at Merrill, constantly asking the heads of various trading desks why they weren't taking on still more risk in pursuit of higher profits. Even as it increased, O'Neal was heard to expostulate that VaR was too low at Merrill, given the "real" risks and the bank's overall objective. Fixed income markets weren't cyclical anymore, O'Neal told board members; risk was a less risky concept. Not for a second did he contemplate the reverse theory: that the models no longer reflected reality.

The methodology used to calculate VaR is also problematic. VaR, like most other risk management models, is based on a series of assumptions, which in turn depend on probability and statistics. That means that VaR is shaped by what has happened in the past, and more specifically by what has happened most frequently. In some cases, there are a lot of data to draw on: the real estate market, for instance, has more than a century of reasonably reliable data, while the bond market has seventy or eighty years' worth. At the other end of the spectrum, risk managers can draw on only five years' worth of robust data available on credit default swaps, the newest breed of derivatives, which played a critical role in the market meltdown. VaR places more reliance on recent history than it does on the broad sweep of past events, but the biggest shocks have no historical precedent. As Greenspan sadly admitted to Congress, the models weren't designed around periods of maximum stress. Had they been, bank capital requirements would have been higher. Instead, Greenspan opined, "the whole intellectual edifice [of risk management] collapsed."[12]

VaR also relies on probability. The more frequently an event has occurred in the past, the greater weight it is given in VaR. (Another problem: the more time elapses between market crises, the fewer bankers and traders have actually witnessed extreme events; by 2008, only a tiny handful of former financiers recalled the events of 1929, and almost none of them were still working actively on Wall Street.) By definition, therefore, VaR discounts the risk associated with an extreme event such as the 1987 stock market crash or Long-Term Capital Management's collapse. But while those are statistically unlikely to recur, such "unknown unknowns" are exactly the events that are the most destabilizing and thus the most critical to risk managers. Nassim Nicholas Taleb became just as famous as John Paulson (if not as wealthy) following the publication of his book The Black Swan: The Impact of the Highly Improbable, which points out just how frequently those events occur. Before the rest of the world "discovered" Australia, all swans were white; every empirical observation over the course of millennia supported that proposition. And yet, as the discovery of the first black swan in the antipodes proved, it was a false theory.

It was what Lehman's risk managers couldn't imagine, because it was outside of the realm of their knowledge, experience, or the all-important data, that would lead to the firm filing for bankruptcy two years later. In Taleb's view, these "Black Swans" are far more common than we'd like to think, and the biggest risk management flaw of all is the fact that we are so reluctant to admit that there is no such thing as a perfectly functioning crystal ball. Could someone in 1900, with the knowledge that was available as of that date, have predicted World War I and its consequences, including the Third Reich and the rise of the Soviet Union? he wonders. Of course not. The knowledge of the future available to a citizen at the dawn of the twentieth century was as limited as ours is today. That has ramifications for trying to manage risk on Wall Street. "In finance," Taleb concludes, "people use flimsy theories to manage their risk and put wild ideas under 'rational' scrutiny."[13] Black Swans are, by definition, impossible to quantify until they have occurred and thus become knowable. by which time it's too late.

Those who rise quickly to positions of power on Wall Street these days tend to be people with strong mathematical skills and a natural quantitative bent, because that's what it requires to come to grips with the complex financial instruments that dominate today's financial system. These individuals gravitate to quantitative tools for help in understanding risk. When they spot a possible Black Swan rising like a storm cloud on the horizon, their first instinct isn't to ask themselves the most basic question: "What might this be? Is it something I recognize, or is it something new that is going to force me to alter the way I think about the world?" Instead they plunge into their comfort zone—quantitative analytics—to see if they can make sense of this mysterious cloud. By the time they realize they can't, that it's something new and very ominous indeed, it's too late.

Even after the collapse of Bear Stearns and Lehman Brothers, in which liquidity risk had played a major role, bankers still continued to focus far more attention on credit risk and operational risk than on developing methods for predicting whether liquidity is about to evaporate. Ironically, the level of risk associated with flawed models (including risk management models) was even less of a priority, something that only 58 percent of respondents attempted to manage, according to a survey conducted by accounting giant Deloitte in late 2008.[14]

Quantitative risk measurement and management tools will remain problematic as long as financial institutions have a vested interest in interpreting the results the way they feel best helps them continue to pursue profits at all costs. A firm with a high VaR can reassure itself that its traders are better than their rivals at managing that risk, so the level or rate of increase is nothing to be concerned about. Moreover, as long as that high VaR is accompanied by a jump in revenues and profits from taking the risks, what is there to worry about? For Sir Deryck Maughan, plenty. At an industry conference in December 2009, the British banker, now a partner at KKR, warned his colleagues that many of the mathematical models that had led financial institutions to discount or overlook what proved to be toxic risks were still being used. The industry, he said, had not "faced up to the intellectual failure of risk management

systems, which are still hardwired into many banks and many trading floors."

Above all, regulators still worry that the banks will try to compute VaR in such a way as to reduce their capital requirements. Since financial institutions can make money only on capital that can be used (and the leverage that they can apply while using that capital), the lower their capital requirements and the greater the capital they can use, the more likely the bank or investment bank is to generate an outsize ROE. That potential global competition to have the lowest possible capital, warned Sheila Bair, chairman of the Federal Deposit Insurance Corporation, in a June 2007 speech, "is a game with no winners." Bair worried that the Basel approach came too close to letting banks set their own capital adequacy standards, an approach she compared to letting each football player set his own rules in a championship match.

Bair's warnings, and her subsequent contributions to the debate over Wall Street's future, identify her as perhaps one of the most prescient Wall Street regulators of the last quarter century. At the time the Basel II signatories agreed to this approach, markets were unusually benign, volatility was at very low levels, and bank profits were strong and rising. That alone should make regulators think twice about what constitutes an acceptable level of capital, she cautioned. There is a "danger [in] thinking that banks will have enough lead-time to ramp up their capital as economic conditions deteriorate."[15] In light of the events of the next eighteen months, which included frantic and sometimes failed attempts to replace capital being eroded by write-downs, those remarks are striking. Bair, it seems, was able to do what Wall Street's best and brightest minds couldn't: envisage a day when the future might not be as rosy as the present. But then, regulators don't get bonuses for delivering profits to the banking industry.

The Lemmings, the Cliff, and the Laws of Physics

In 1831, well-trained English troops were marching in step across a

suspension bridge near Manchester when it suddenly collapsed. Those assigned to investigate the tragedy discovered that the reasons for the collapse were tied to the laws of physics. British soldiers were drilled rigorously until they could march impeccably in step, or cadence, as it's known. But when it came to crossing the newly designed suspension bridges, this pattern proved to be disastrous. In some cases, the cadence of the marching can match the natural resonance frequency of a suspension bridge; in those cases, even though each step adds only a tiny amount of energy, cumulatively the impact of so many marching soldiers in cadence puts so much stress on the structure that the result is devastating. Once engineers realized what was happening, they set about devising new kinds of alloys that would reduce the natural resonance of a bridge to the bare minimum. Meanwhile, military officials recognized that marching in step, however desirable in nearly every other circumstance, was a foolish risk to take when crossing suspension bridges; they began instructing their troops to break cadence when crossing bridges.

This famous example of one of the laws of physics at work has an uncanny similarity to Wall Street. A Wall Street institution's employees are trained to pursue ROE at all costs, almost blindly, in the same way that soldiers are drilled to march in cadence, until it becomes second nature. Neither group questions the nature of that training until something goes wrong. In both cases, the result is a high level of systemic risk that no quantitative model can capture until it's too late. Just as each soldier concentrated only on making sure his steps exactly matched those of his fellow soldiers ahead of and on either side of him, on Wall Street few people seemed to pay attention to anything beyond the transaction at hand and its role in maximizing their group's profits and the firm's return on equity.

The groupthink worried Myron Scholes, coauthor of the Black-Scholes valuation formula, which made it possible for options and all kinds of other complex derivative products to find a home on Wall Street. Scholes (whose formula is the subject of much scorn from critics such as Taleb, who argue that it makes risk appear too understandable and too quantifiable) points out the inherent

riskiness of ignoring systemic risk. “Any one bank can measure its [own] risk” using models based on Black-Scholes or other research, Scholes notes. “But it also has to know what the risk taken by other banks in the system happens to be at any particular moment.”[16] In other words, just as no drill sergeant today would insist that his soldiers march in cadence at all times, regardless of the circumstances or the terrain, no financial institution can afford to ignore the possibility that what appears to be a riskless transaction in isolation can create risk to both the institution and the system if it’s repeated endlessly across Wall Street. One bank doing subprime CDOs wasn’t going to torpedo the financial system, but the banking system en masse cranking out so many subprime CDOs that subprime lending became the tail that wagged the dog came perilously close to doing just that.

That kind of copycat behavior also damaged regulators’ efforts to rein in risk, recalls Sheila Bair. The banking regulator had a “peer intervention” analysis that was designed in the expectation that one banker had a better chance than a regulator of figuring out if another banker was taking on too much risk. The problem was that so many institutions were doing exactly the same thing, and the problems weren’t flagged. Everyone was doing it; it was the new normal and everyone was making money doing it. No one caught on to the risk management flaw, Bair told the FCIC commissioners, “until the risky activities undertaken by all became unsustainable.”

Wall Street needs to break out of its old ways of thinking about risk and leave behind the notion that it can always be identified, quantified, and controlled. What is needed more than a risk management system is a risk-aware culture, as Deloitte advocated in its survey. Those institutions the accounting firm spoke to in the latter months of 2008 were already aware that their risk management programs weren’t doing a good job for them. Fewer than half of the respondents believed that those risk programs offered “significant value”; nearly a third told surveyors that risk management didn’t generate any value when it came to either boosting the quality of their earnings or improving risk-adjusted returns. Only 38 percent believed their risk management systems

helped limit losses when risks rose to the surface.[17] Indeed, almost the only area in which financial institutions felt that risk management programs were of significant value was keeping regulators happy.

Alan Greenspan may blame models for risk management failures, but it was human beings who devised those models, established their core assumptions, and then interpreted the results. As Sheila Bair had feared, there were ample incentives for misreading the level of risk in the financial system. Not surprisingly, most of them revolved around the two core drivers of everything else that happens on Wall Street—fear and greed. In this case, the fear was of being left behind in the battle for market share, profits, and return on equity, while greed was the allure of outsized bonus checks in exchange for taking risks and discounting the lurking presence of a Black Swan event that couldn't be quantified anyway. In presenting the final FCIC report in late January 2011, panel member and former CFTC chair Brooksley Born pithily described what followed as risk management turning into "risk justification." When the upside payoff was potentially enormous, and the downside risk looked slight in terms of probability if not impact, then why not just set the real warning signals to one side, quietly, safely out of sight? In any event, the only way to rein in risk taking, many risk managers argued, was itself behavioral. "Top managers and directors need to keep asking how the bank is making this money, whether the business is sustainable, what assumptions is the risk taking based on, can we get clear and accurate and objective information on the business and its risks," argues one banker turned risk consultant.

"Risk models always are a bit deceptive," says Leslie Rahl, the veteran risk manager at CMRA. Let's say there are two portfolios, one of which is full of complex structured products while the other contains only plain-vanilla securities such as stocks and bonds. Both are run through risk management models that show that they have an equal level of risk—something that can happen in periods of prolonged market calm. Rahl says the response should be not to heave a sigh of relief and move on but to become concerned and

ask more questions about why two such disparate portfolios could appear to possess such a similar risk profile. "Until we come up with better methodologies, we have to find a way to adjust what the models say for the elements that the models can't capture," she points out.

Wall Street also needs to find a way to question its own assumptions, not just the conclusions drawn by models. The crisis we have just lived through wasn't as impossible to predict as some Black Swan theorists might argue. The risks associated with subprime lending were clear; as a study by Federal Reserve economists on the crisis showed, many Wall Street analysts correctly predicted that a slump in housing prices would batter subprime loans and the CDOs that contained them. But they ascribed a low probability to that ever happening.[18] "For fifty years, housing prices nationwide had always gone up, even if just a little bit," notes Michael Stockman, formerly a banker at UBS who now advises clients on portfolio construction as a managing partner of Corridor Quadrant. True, there were regional housing slumps, but one of the reasons that bankers felt comfortable giving mortgages to subprime borrowers was their confidence that even if they weren't good credit risks, the value of their collateral—the house they bought—would never deteriorate. Even movements in major real estate indexes were referred to as "appreciation," Stockman notes wryly. "No one could imagine depreciation." Indeed, when prices did fall, the move was dubbed "negative appreciation."

In medicine the adage that doctors first and foremost should do no harm causes physicians to second- and third-guess their original assumptions and send patients to other doctors for additional tests and second opinions. With no professional standard of that kind on Wall Street, there was no motivation for anyone within AIG's head office to query the results that its London-based division, AIG Financial Products, was posting. Between 1999 and 2005, the division's revenues soared 342 percent, to $3.26 billion, as its financial engineers delved into the business of selling insurance to investors in CDOs in the form of credit default swaps. The business proved so successful that by 2005, AIG Financial Products was

generating 17.5 percent of AIG's revenues, up from 4.2 percent in 1999; profit margins on the business had nearly doubled.

Across AIG, there seemed to be the will to believe that this business would be the insurance world's version of the Internet, an innovation that would utterly transform its business by enabling savvy firms such as AIG to sell insurance against credit risk in the same way they insured people against hurricane damage or death. Investors paid their premiums, just as someone buying fire or life insurance did. Because the CDOs AIG was insuring carried top-tier credit ratings, the firm didn't need to worry about setting aside capital to make good on the insurance claim. AIG figured that if CDO quality began to deteriorate, it would be able to respond. In fact, the calls for the firm to post collateral in connection with the slumping values of CDOs mounted faster than AIG could cope with; the firm had forgotten that it's the things that you fail to worry about or assume aren't risks at all that prove most toxic in the long run. AIG's de facto collapse and the more than $100 billion in bailout funds provided by the Treasury Department to keep it at least nominally afloat and prevent its collapse from fatally damaging every financial institution with which it had had dealings is one of the most clear-cut examples of what can happen when Wall Street stops thinking sensibly about risk on both an enterprise and the systemic level.

Enlightened self-interest may not be working to curb excessive risk taking. But Wall Street can't simply pass the buck, either, demanding that others perform this governance and risk management function on their behalf. For starters, it's by no means clear that regulators will do a better job; these days, some of them are likely to be the same former Wall Street risk management executives that stood by, oblivious, as the storm gathered and struck them.

Michael Alix, for instance, trumpeted the resilience of his risk management models and celebrated his risk management system's ability to ensure that Bear Stearns didn't hold too many risky securities at the same time in an interview with a BusinessWeek reporter back in 2006. Even when the markets were falling in

response to a rise in interest rates, a computer screen full of flashing red lights (signaling securities whose prices were declining) didn't alarm him, he bragged. "The machine works!"[19] Less than two years after Alix was named head of risk management at the firm, Bear Stearns proved definitively that the machine didn't work: it hadn't anticipated all the problems that Bear would face or the extreme market conditions.

In one of the irony-rich moments of the Wall Street crisis, Michael Alix himself went on to be named vice president of the New York Federal Reserve's Bank Supervision Group in October 2008, at the heart of the crisis. The appointment raised eyebrows and prompted some scathing comments across Wall Street, where Bear's former rivals were fighting to survive and figure out what to do next. But then, to many observers it was already clear that, far from helping Wall Street to rein in its worst instincts, regulators of all kinds—from the SEC down to the rating agencies—either were unable or unwilling to act or were even more oblivious to the risks than Wall Street itself. Wall Street may have been dancing as long as the music kept playing, in Chuck Prince's words. But to many it seemed as if the central bankers and securities regulators were calling the tunes and turning up the volume.

CHAPTER 7

Washington Versus Wall Street

The story of James Gilleran and his chain saw has become one of the most infamous in the growing annals of regulatory mismanagement of Wall Street. It dates back to the early summer of 2003, long before anyone on the Street realized that there was anything alarming going on in the real estate market, much less in the business of turning subprime mortgages into triple-A-rated packages of securities. Banking regulators were gathering to proclaim their support for the Bush administration's decision to reduce the regulatory burden that made it harder for the institutions they supervised to extend as many loans as they wanted. Gilleran, who had been named to head the Office of Thrift Supervision (OTS) in 2001, knew a great photo op when he saw it. At the press conference, he was one of four banking regulators to pose for dramatic effect behind a stack of paper representing regulations governing the lending business, all wrapped up in red tape. The other three regulators brought garden shears to demonstrate their willingness to attack the problem. In the photograph, Gilleran sported the biggest grin and the biggest weapon: a chain saw.

But then, James Gilleran had a lot of motivation to make his corner of the regulatory jungle happy by cutting red tape: the prospect of millions of dollars a year in fees from institutions that elected to operate a savings and loan institution, or thrift, as these entities are known. Just as the investment banks had every incentive in the world to maintain the lowest possible amounts of capital on their books, so many regulators—especially smaller, newer, and less well-known entities such as the OTS—had a built-in reason to lower their regulatory standards and overlook risky

behavior on the part of their regulatees in an effort to woo and retain "clients." Anyone familiar with the basic rules of organizational behavior could have predicted this would happen. OTS's budget depended on the number of institutions it regulated. The more institutions it could attract under its regulatory umbrella, the better it would fare, organizationally speaking. On the other hand, if it adopted a regulatory stance that its "customers" viewed as unduly harsh, a number of thrifts might suddenly decide that they were really commercial banks at heart and thus subject themselves instead to the oversight of the Office of the Comptroller of Currency (OCC) and the Federal Reserve.

This was exactly the kind of development that the FDIC's Sheila Bair had feared—that lax regulation and a less-than-rigorous approach to risk management would cause the lowest common denominator to triumph. Gilleran kept slashing away at both regulations and his own ability to enforce whatever ones remained on the books, in hopes of wooing more "clients." Even as the mortgage lending business—a big part of the savings and loan industry—swung into high gear, Gilleran's chain saw whirred into action: the OTS honcho cut the size of his staff by 25 percent.

OTS-regulated institutions became the biggest providers of the mortgages that would end up contributing most to the subprime meltdown, such as option ARMs (adjustable-rate mortgages), but complaints about predatory lending didn't seem to register on Gilleran's radar. As is now well known, it was during Gilleran's tenure that the worst of the flawed mortgage products made their debut; complex loans that borrowers didn't understand committed them to larger mortgage payments than they would be able to make. Only reluctantly did OTS later sign an OCC-orchestrated pact to halt the practice.

John Reich, who took over the helm of OTS from Gilleran in 2005, showed nearly as much zeal as his predecessor had done in the quest to make the organization the regulator of choice for America's financial institutions. His publicly voiced concern about the risk that overregulation would penalize both lenders and borrowers and keep Americans from the dream of owning their

own home must have been music to the ears of Angelo Mozilo, CEO of Countrywide Financial.[1] By 2005, Mozilo was a bit fed up with having to account for all his actions to the OCC. The latter, as the Washington Post later reported, didn't want Countrywide's senior officers deciding which appraisers should be chosen to calculate the value of the properties against whose value Countrywide was lending money and structuring mortgages. Logically enough, the OCC feared that that presented a conflict of interest: appraisers might come back with inflated valuations that would allow Countrywide to write more loans and pocket more fees from selling them (and the risk they entailed) on to investment banks and commercial banks to be repackaged into CDOs. In

2006, Mozilo decided to leave the pesky OCC behind and to become a thrift, subject to the more benign regulation of the OTS. Its new regulator had, Countrywide executives later said, promised to take a more "helpful" view of the appraisal selection process.[2] It proved to be a classic example of what became known as regulatory arbitrage.

Indeed, it wasn't a coincidence that OTS ended up as the regulator of choice of many of the financial institutions that took on the greatest risks in subprime lending and would later pay the ultimate price for their risk management failures and the regulatory shortsightedness of Gilleran and Reich. For years, the OTS's single most important client was Washington Mutual (WaMu), the feisty thrift that had built up a nationwide banking network and was writing mortgage loans as fast as it could. The OTS certainly didn't want Washington Mutual to leave its regulatory embrace. Perhaps that was why its regulators allowed the institution to slash the amount of capital it allocated against possible future loan losses more and more with each year that passed, even when it became clear that the risks associated with the real estate business and mortgage lending were rising. By the summer of 2005, loan loss reserves at WaMu were a mere $48 for every $10,000 in mortgage and personal loans, about 25 percent below the already low average level for savings and loan institutions regulated by OTS.[3] Not surprisingly, in what would prove to be their final fiscal year as

independent institutions, fees paid by Washington Mutual and Countrywide together accounted for nearly a fifth of the OTS budget.

One of the other institutions of which the OTS ended up as a major regulator was AIG, the giant insurance company that would become one of the biggest casualties of the Wall Street mayhem. As an insurance company, AIG was regulated by state agencies rather than federal banking or securities regulators. But it owned a savings and loan institution, and that meant the OTS received all the financial information about the company's operations. The OTS had warned AIG's board that its risk management procedures were full of holes. Nonetheless, when Federal Reserve officials put in a series of emergency phone calls on the critical weekend in September that led to the Lehman Brothers bankruptcy and the sale of Merrill Lynch, their OTS counterparts sounded downright bewildered to hear from them.

The OTS was unaware of the fact that within the next two weeks AIG would face a demand for nearly $40 billion in cash from its counterparties to offset the declining value of the securities it had posted as collateral. The losses were in AIG's financial products division, which wasn't regulated by the OTS; still, given the magnitude of the obligation, they would certainly wreak havoc on the company's insurance and thrift operations. That would be even more true if, as seemed likely, AIG had to file for bankruptcy as a result of the losses. (Such a filing was averted only at the last moment by one of the largest direct infusions of government cash of the entire crisis.) The OTS couldn't even begin to help its fellow regulators unravel the mess; the Fed decided instead to summon AIG's CEO, Robert Willumstad, to help it understand the magnitude of the problem.[4]

The OTS approach to regulation ended up as the focus of an audit report by the Office of the Inspector General at the Treasury Department. The latter concluded that OTS-supervised thrifts were able to file misleading statements about their financial position, in particular the amount of capital they held on their books. While IndyMac—which collapsed in July 2008—was responsible for its

own fate, the report says, the OTS had an opportunity to rein in the institution's hyperaggressive lending as early as 2005, when cash flow problems first surfaced.

The report is a review of several occasions on which the OTS permitted the institutions they regulated (including IndyMac) to backdate new capital infusions into the mortgage lending institutions, making their balance sheets look more stable than was really the case. In the case of IndyMac, that made the thrift look healthy only two months before the FDIC had to step in, close the doors of the suddenly insolvent institution, and reimburse its depositors. Even though at times IndyMac's thinly staffed regulator had up to forty people peering over the shoulders of the thrift's managers, the Treasury Department's forensic accountants concluded that they all either missed or didn't care about IndyMac's reckless behavior. (This included failing to verify that developers it was lending to had nailed down funding for all their projects and not overhauling its lax appraisal process for residential mortgages.) What did matter to OTS? "Growth and profitability [were] evidence that IndyMac management was capable" of managing their business and its risks, the report's authors concluded.[5]

Of course, other regulators weren't exempt from this.

Playing the Blame Game

When Wall Street's misaligned compensation policies set up incentives almost guaranteed to wreak havoc on the financial system, and when its internal risk management systems and models failed to work the way everyone believed they would, the theory was that the regulators and legislators—"Washington," for short—should have been able to prevent, control, or manage the crisis. After all, the raison d'être of the entire regulatory system is to serve as a last-ditch line of defense, one protecting the integrity of the financial system from Wall Street's worst instincts, referred to on the Street itself as "animal spirits." It was logical that investment banks were cheerleaders for their own interests. But the financial system

needed its own team of cheerleaders—or guards—and that role is supposed to be played by the regulators. These groups, including the OTS, were established to protect the health of the system, because of the importance of the money grid to the economy and even to society as a whole. They weren't there to help individual businesses maximize their returns or to promote the philosophical concept of free enterprise.

Chuck Prince, the CEO of Citigroup until his ouster in the fall of 2007, might insist on continuing to dance to the music that he heard. But it was a regulator's job to ask whether the music that he claimed to hear was real or playing only in his head. And if exhausted musicians were collapsing one by one on the stage even as the Wall Street CEOs continued to polka, then the task of a regulator was to step in and declare that the party was over. A well-functioning regulatory system is one that is able to detect when the music is out of tune, when half the musicians can't keep up with the dancers, and when the dancers are cavorting to imaginary tunes.

On an unseasonably warm and balmy St. Patrick's Day in 2009, exactly a year after the collapse of Bear Stearns began the final chapter in the meltdown, some of Wall Street's survivors headed to the Upper East Side of Manhattan. They were bound for Rockefeller University's Caspary Auditorium, site of a sold-out Oxford-style debate about the causes of the financial crisis, sponsored by Intelligence Squared, a nonprofit organization backed by a hedge fund manager, Robert Rosenkranz. The resolution up for debate that evening: "Blame Washington more than Wall Street for the financial crisis." If it weren't for the occasional splash of green in the audience, no one would have known that the day was one that other New Yorkers were celebrating. In contrast to Intelligence Squared's other monthly debates, audience members hadn't come to this one to be entertained or even educated. They were cross, worried, and anxious; they wanted to vent. "I just know that I wasn't responsible for all this mess," said a twentysomething laid-off banker who gave his name only as Pete, his anger palpable. "We're the most hated guys out there. No one believes us. Even the president tells us we're shit. Come on! It can't be all about Wall

Street!"

Indeed it can't, economic historian Niall Ferguson reassured Pete and others like him at the beginning of the debate. Ferguson admitted that he hadn't come to praise or defend bankers. "We blame them for much of what has gone wrong," he told the audience. "It's just that we blame the politicians more." The Wall Street hometown audience erupted in laughter and cheers; declaring open season on Washington is universally popular. As for Citigroup's Prince, who claimed Wall Street had no option but to get up and dance, Ferguson pointed out slyly, "You have to ask yourselves, ladies and gentlemen, who was playing the music." Why, the historian wondered, do politicians love to point their fingers at financiers in times of trouble? "Could it just possibly be that they're trying to divert our attention away from Washington's own responsibility for the debacle?"

The possibility that the fatal flaw lies outside Wall Street itself is a comforting one to many financiers, especially as they confront the specter of heavy regulatory reforms. "Blaming Wall Street is like blaming the atmosphere for thunderstorms," exclaimed John Steele Gordon, part of Ferguson's debate team arguing in favor of the motion. Street "panics" happen periodically, he pointed out. "It's the nature of the beast." On the other hand, Washington regulators are "supposed to be the guys with the striped shirts and the whistles on the playing field. They make up the rules, and then they enforce them. And then they sometimes change the rules in order to accommodate some of their friends."[6]

It was an uneven contest: Ferguson and his two allies won the debate hands down, helped in equal parts by their debating skills, Ferguson's charm and Scottish accent, and the audience's determination to heap more of the blame on Washington, an attitude that reminded some observers of the age-old children's protest about being punished for a misdeed: "But, Mom/Dad, he made me do it!" Certainly, those New Yorkers seemed ready to believe that Washington made them do it: before the debate, 42 percent of attendees had voted in favor of the motion that Washington was more at fault than Wall Street, but two hours of

debate later, 60 percent agreed with the proposition. Nearly ten months later, a somewhat cooler-headed Jamie Dimon insisted that, on the contrary, the buck stopped with Wall Street. "I do not blame the regulators," he testified before the FCIC hearings in January 2010. "The responsibility for a company's actions rests with the company's management." But there were still many to disagree with Dimon, to question whether Dimon believed his own argument, and to argue that Washington had actively urged Wall Street to pursue risky strategies, or at least served as an enabler of sorts.

Awarding the lion's share of the blame for the financial system's near meltdown to Washington rather than Wall Street is tempting, but it's also overly simplistic. True, Wall Street's regulators didn't try very hard to rein in the festivities at the height of the boom; some, such as Gilleran and the OTS, seem to have egged their constituents on to greater follies. But by the time the crisis was taking shape, the ability of regulators to fulfill their traditional role of protecting Wall Street's core functions—the smooth transfer of capital from those who had it to those entities that needed it—had been steadily eroded by several decades' worth of policy decisions. These culminated in a dysfunctional regulatory system that was rarely able to move beyond the nuts and bolts of each individual decision—separating research and investment banking divisions, moving to decimalization in trading systems, banning an "uptick" rule, promoting home ownership, fighting the prospect of an economic slump by keeping interest rates at rock-bottom levels for years, allowing parts of the financial system to shop for their own regulator—to focus on the big picture.

And when the big picture was mentioned, that picture wasn't one of the maintenance of a financial utility. No one discussed whether those initiatives contributed to the long-term health and stability of the financial system. Regulating other utilities is relatively straightforward, in both theory and practice, in part because there's a general acceptance among all interested parties that there is a broad public interest in having a reliable source of gas or electricity and an ample supply of clean water. (That's particularly true

because most regulatory agencies are established to police the behavior of monopolies or oligopolies providing services that society deems to be essential.) Even the managers of power plants and water companies that might have an interest in keeping costs low and maximizing profits know that they will personally suffer alongside everyone else in the community if those financial goals result in the power grid collapsing or the water becoming contaminated.

When it comes to Wall Street, however, the picture is far blurrier, and not just because no single Wall Street institution can lay claim to monopoly or oligopoly status. Wall Street isn't a business like any other; it can't be compared to retailers such as Walmart or consumer goods manufacturers such as Colgate-Palmolive. Even critics of excessive regulation will admit, especially after the events of the last few years, that all members of society have a vested interest in the survival of the financial system that can't be compared to even those giant corporate entities. (After all, we can always go shopping at Target.) Anyone who quibbles with that may want to discuss their views with the citizens of Iceland, who saw their own money grid almost completely disappear; some Icelanders returned to fishing to keep food on the table as the country's three McDonald's franchises closed their doors—good for the country's nutrition, doubtless, but a blow to its economy and psychology. It's deceptively easy for anyone to decide what makes for a good regulatory outcome in other utilities (clean water flows through the water pipes; electrical power is delivered when needed and in the quantity required to meet the demands of even the hottest summer days), and a failure is equally easy to spot (a blackout, for instance).

But on Wall Street, what makes for a good regulatory outcome is far more nebulous. Even the events of 2008 are subject to debate. Did they signify the failure of the regulatory function, because several major institutions collapsed, others required hundreds of billions of dollars of taxpayer capital to survive, and the entire money grid came within a fraction of an inch of the brink of disaster? Or was it a success, because legislators and regulators were

able to pull together in a remarkable last-ditch effort in the worst days of the autumn of 2008 and rescue the most systemically important institutions, those deemed too big to fail? The definition of a good regulatory outcome is equally subjective. Ask an investment banking shareholder, and he will likely reply that a hands-off approach by regulators that allows the companies whose stock they own to capture a bigger market share and maximize their profits is the most desirable system. Corporations want a system that provides them with low-cost access to capital, even when the transactions that they seek to complete are ones that are uneconomic for Wall Street to undertake. Money managers and individual investors want a system that protects them from Ponzi schemes and other abuses.

The very disparate views of the goals of financial market regulation were part of the problem. Another major reason that the financial system would be left unguarded and unprotected (in the eyes of some, at least) at a crucial juncture was the fact that to many on Wall Street, the laudable goal of protecting the money grid required tolerating the intolerable: government intervention. By the dawn of the twenty-first century, the kind of deregulatory fervor that James Gilleran displayed in taking a chain saw to symbolic and actual red tape wasn't an anomaly but part and parcel of the political and regulatory ethos in the United States.

For government intervention in the shape of regulation to be acceptable, the proposed rules must be able to clearly demonstrate their value in advance, this camp argued, a burden of proof that was hard to meet. The FDIC's Sheila Bair admitted that when banking supervisors had to rely on judgment, the absence of clear reason for concern—such as losses from the risky activities—made it difficult to intervene. "Without hard evidence that the activities were creating unwarranted risk," trying to clamp down on risk taking would have been a provocative move, Bair suggests. (It would also have ignited a firestorm of controversy: Why were regulators seeking to meddle in a profitable business run by talented professionals?) "In retrospect, it is clear that supervisors were not sufficiently forward-looking in identifying and correcting

imprudent risks," Bair testified at the FCIC hearings. "Current profitability alone is not a sufficient measure of safety and soundness." Indeed, profits—particularly the kind of record profits posted in the six straight years between 2001 and 2006—can be a red flag alerting a vigilant regulator to risky business. Only briefly, in the aftermath of the chaos made worse by the simultaneous failure of incentives, risk management, and regulation, was it philosophically acceptable to talk about preemptive regulation—protective regulation—once more.

Washington and Wall Street have coexisted uneasily for as long as there has been an independent national government and a national financial system. As long as financial markets have existed, what happens within them has consequences not only for the financiers but also for citizens who are far removed from Wall Street and who would be hard-pressed to distinguish a stock from a bond when asked to do so, much less define a derivative. The current crisis has wrecked the national economy of Iceland and caused havoc in German towns; everyone from marketing executives at consumer product firms to managers of geriatric nursing homes has had to rewrite frantically budgets to cope with the financing crisis that ensued. New college graduates, retirees, and entrepreneurs have seen their dreams shattered. Some economists calculate that the cost of the current crisis may reach as much as $4 trillion. That is a high price to pay for the de facto failure of governance, risk management, and regulation. American citizens, regardless of their level of wealth or personal opinions on the merits of regulation or government intervention, will end up paying for the government bailouts of Wall Street institutions and regulatory shortcomings in the form of higher taxes or lower government spending on other projects for years to come.

Deregulatory Fervor and Unintended Consequences

It shouldn't have been this bad. In the wake of the 1929 market crash and the nationwide depression that followed a wave of bank

failures in the 1930s, politicians recognized the impossibility of controlling the fear-and-greed cycle that has governed financial dealings for centuries. People, left to their own devices, will fuel future bubbles, they knew, whether the focus of runaway speculation was tulip bulbs or railroad stocks. But, they reasoned, the federal government could put in place a set of institutions whose function was to take a pin to those bubbles (or even find a way to let the air gently out of them) before they could become so big that when they burst they would wreak havoc on the entire system.

In the 1930s, a battered and disgraced Wall Street had little ability to object to the array of reforms and regulatory measures introduced by Washington. When Congress passed the 1933 Glass-Steagall Act mandating the separation of commercial banks (entities taking deposits from individuals and businesses) from investment banks (those banks engaged in the riskier business of trading or raising capital via the debt and equity markets), even J. P. Morgan's heirs bowed to the inevitable. In September 1935, a clutch of J.P. Morgan office boys pushed eighteen heavy wooden rolltop desks out the doors of 23 Wall Street, the building at the corner of Wall and Broad that the financier had occupied from the day it was built until his death in 1913. They shoved them up a slight incline, past the New York Stock Exchange on their left, to the doors of a newer building at the corner of Wall Street and Broadway. A new investment bank, Morgan Stanley, had been born, in response to Washington's demand for risk reduction.

But Wall Street was never comfortable with the extent to which regulators restricted its collective ability to seek out new sources of business and profits. Every time a financier was blocked from doing something new and creative, he chafed at what felt like senseless and burdensome regulations. With the passage of decades and the disappearance of those who could all too vividly recall the horrors of the crash and the Depression, even rules like Glass-Steagall seemed increasingly unnecessary. With the transformation of Wall Street's business during the 1970s, and in particular as increasingly powerful competitors arose in Europe and Japan, Wall Street's

leaders began viewing regulation as not only something that blocked their firms from earning as much as they could, but something that would lead, inevitably, to the loss of market share to overseas rivals and the erosion of Wall Street's unquestioned dominance of global markets. Banks such as Deutsche Bank and Credit Suisse didn't have to worry about Glass-Steagall, they fretted. They had giant balance sheets, the likes of which Morgan Stanley, Goldman Sachs, and Salomon Brothers could only dream about. Happily for Wall Street, this growing disgruntlement on its part coincided with the rise to power of a group of politicians with a distaste for regulation that, if anything, exceeded that of the financiers.

Ronald Reagan's vision of America harkened back to a golden age of sorts, around the dawn of the twentieth century, when American lives were lived around the town square and the country store, where the Fourth of July was celebrated sedately and joyously with picnics of fried chicken and blueberry pie followed by fireworks after dusk. Free enterprise was part of being a free man or woman, in this worldview, and Reagan had an apparently endless series of witty and damning bons mots about the evils of government intervention. "The nine most terrifying words in the English language are, 'I'm from the government and I'm here to help,' " Reagan quipped on one occasion. As for the government's view of the economy, that was easy to summarize: "If it moves, tax it. If it keeps moving, regulate it. And if it stops moving, subsidize it." Reagan's view of regulators themselves was equally jaundiced. "The best minds are not in government," he declared. "If any were, business would hire them away."[7] Reagan's philosophy resonated deeply on Wall Street. Freedom, the new president proclaimed, was a core American value. Didn't that include the freedom from regulation for those on Wall Street?

Free market fundamentalists, as George Soros dubbed them, rose to power in the Reagan era but weren't confined to the Republican Party. When the Democrats took control of the White House and (briefly) Congress in 1992, policy toward Wall Street continued to revolve around deregulation, with few interruptions. (Robert Rubin,

who later prodded Citigroup's bankers to take more and more risk at the height of the bubble, was a Goldman Sachs alumnus appointed by President Clinton to run the Treasury Department; not surprisingly, he advocated a hands-off approach to regulating Wall Street.) The free market fundamentalists argued that the managers of Wall Street's financial institutions were the people best suited to understand what was going on and to identify the real risks. And they had incentives to be prudent: if they weren't, investors and analysts would hold them to account. Missing from that analysis were the facts that Wall Street leaders also had an incentive to downplay the risks they identified, that their shareholders had a tendency to view a half-empty cup as two-thirds full, and that analysts were justifiably wary of the career risk associated with slapping a buy rating on any stock, much less on a Wall Street power player.

Increasingly, policy makers and legislators seemed to overlook the fact that an underregulated Wall Street could create havoc that wasn't confined to the financial system itself but stretched well into the broader economy and society. In other words, it wasn't just their own fate for which Wall Street firms were responsible. In the same way that a pharmaceutical company that didn't test its drugs properly (and didn't have an effective FDA overseeing those tests) would not only blow itself up but cause active harm to the general public, so the collapse of a Wall Street firm could have far broader consequences.

History spelled out the message quite clearly. The nineteenth century was punctuated by a regular series of panics on Wall Street: one in 1819, another in 1837, and still another in 1857. The Panic of 1873 (caused by a toxic combination of events that ranged from the railroad bubble to the effort by financier Jay Cooke to corner the gold market and his subsequent bankruptcy) led to a six-year-long national depression; the conflict between labor and management that followed it lasted well into the twentieth century and can be traced back to the decision of President Rutherford Hayes to use troops to break a strike by railroad workers. (Scores were killed.)

The 1873 crash caused bankruptcies across the United States and put an end to post–Civil War Reconstruction in the South; there was no money to continue political and economic reforms, meaning that African Americans in many former slave states were forced to wait another century to exercise their right to vote. The 1873 panic was followed by a boom revolving around more railroad speculation—which in turn produced yet another panic in 1893. That financial and economic crisis caused mayhem in eastern and midwestern manufacturing centers and sent displaced workers drifting westward to populate western cities from Portland to San Diego. One nineteenth-century panic caused the collapse of more than a dozen railroads; a later one was responsible for the demise of some six hundred banking institutions. In all cases, leverage was one of the culprits.[8]

Then came the Panic of 1907, an event that offers some uncanny parallels to the events of a century later: the complete disappearance of liquidity from financial markets, the collapse of one of Wall Street's largest financial institutions (the Knickerbocker Trust Company), the phenomenon of contagion as the crisis rippled through the system from one financial institution to the next, and the unwillingness of New York banks to extend even short-term credit.[9] Only the intervention of J. P. Morgan himself, playing the role of the then nonexistent Federal Reserve, saved the day. Summoning Wall Street's best and brightest to his Wall Street offices, he commanded them to cough up $25 million in the next ten minutes to keep the stock exchange open or watch the financial system itself collapse. Within half an hour of the arrival of the first banker at Morgan's offices, $23.6 million had reached the stock exchange; liquidity had been restored.

Morgan had saved the day, but his actions had created two separate sources of concern that led directly to the creation of a regulatory institution that could fill the role that Morgan had: the Federal Reserve. There were widespread fears that Morgan's power—so dramatically revealed—could be misused. Those who didn't worry about Morgan himself were concerned that after his death (which came in March 1913, months before the Fed's creation)

there would be no other single individual with the same blend of skill, judgment, power, and force of character to perform the same function in the event of future panics. A regulatory agency was the solution that addressed both sets of concerns.

The chain of events that began in the summer of 2007 reminded even die-hard free market fundamentalists that in the midst of financial panics, regulation and regulators had their uses. Henry "Hank" Paulson, the former CEO of Goldman Sachs, had pleaded for years that Wall Street be allowed to regulate itself. Appointed Treasury secretary in 2006, he remained a staunch advocate of free financial markets. "An open, competitive and liberalized financial market can effectively allocate scarce resources in a manner that promotes stability and prosperity far better than governmental intervention," Paulson told an audience at the Shanghai Futures Exchange in the spring of 2007, a speech that was seen by global economists as part of an ongoing campaign by the United States and U.S.-based financial institutions to persuade China to follow their lead at a faster pace.[10] (China had already introduced new products such as foreign-exchange derivatives contracts and expanded its bond market, but it was slower in developing its asset-backed securities market and still imposed constraints on the local activities of U.S. financial institutions.)

Within eighteen months, Paulson was down on one knee in front of Nancy Pelosi in the Oval Office, begging for her help to get Congress to pass an unprecedented bailout package, one that would involve massive government intervention, to save the financial system from disaster. Meanwhile, the effort to preempt global competition had begun to look like an academic exercise. For now, at least, giant financial institutions had to worry more about surviving than about losing market share. And in China, local regulators were learning a lesson that their U.S. counterparts might have absorbed in 1873, 1893, 1907, or 1929. "Financial innovation is a double-edged sword," Fan Wenzhong, deputy head of research at the China Banking Regulatory Commission, said at a September 2008 conference in Beijing. "We can't just concentrate on product innovation and overlook the need to build the financial system."[11]

But by the time Paulson learned that regulators and legislators (however flawed the individuals themselves might be) might have their virtues when it came to serving as a counterweight to the worst excesses of Wall Street's "animal spirits," it was late in the day. The regulatory framework had been established early in the twentieth century as a way to prevent another financial markets panic. But over the last twenty-five years, either the power of regulators to act had been curtailed or those individuals installed at the helm of regulatory agencies were unwilling to act.

Even if the new breed of regulators installed by the deregulatory zealots could bring themselves to admit that something more than just another normal market hiccup was taking shape, their hands-off philosophy left them powerless and paralyzed. Just as bankers used magical thinking to reassure themselves that the heavy winds and choppy seas they saw weren't a category 5 hurricane taking shape, regulators tried to convince themselves that the free market fundamentalists had it right and another panic wasn't on the way—it couldn't be, because an article of their faith was that market discipline would prevent any financial institution from taking silly or ill-considered risks. (Sheila Bair of the FDIC might note after the storm that a belief in self-regulating, self-correcting market was a fallacy; until that had become obvious, however, that view would have been deemed heretical by any in a position to act on it and beef up regulation.) By the time the storm made landfall, it was too late to act.

In just one example, the formal repeal of the Glass-Steagall Act in 1999 (after years of steady erosion) had helped create banking institutions that the Fed and the Treasury Department now realized were too big to be allowed to fail. Bailouts of AIG and the injection of billions of dollars of new capital to maintain institutions that might otherwise have collapsed, such as Citigroup, are part of the price that American taxpayers and businesses will have to pay for failing to protect the money grid. But the consequences of the near collapse of the money grid are liable to be far more dramatic and long-lasting than those of the actual collapse of the electricity grid in the northeastern United States and parts of Canada in the

summer of 2003. The latter event, a daylong blackout, was unpleasant and caused chaos as well as millions of dollars of losses in spoiled food and lost business. But restoring the power grid to full effectiveness is a matter of willpower, capital, and equipment. Restoring the financial grid to health will take longer and cost trillions of dollars. And when it's done, Wall Street, and our relationship with it, will never be the same again.

Unintended Consequences

Perhaps someone should have warned these avid deregulators of the law of unintended consequences. But even in cases where a specific deregulatory measure didn't have unintended consequences (on which more later), the cumulative effect of the deregulatory ethos was such that over time, the idea that it might be appropriate or acceptable to regulate Wall Street became less and less politically acceptable. "If government appoints as regulators those who do not believe in regulation, one is not likely to get strong enforcement," economist Joseph Stiglitz pointed out in his testimony to Congress. Ultimately, those who did believe in regulation and who managed to survive within that kind of system found it difficult to actually regulate. Meanwhile, Congress—even before the financial crisis hit and the Madoff scandal dominated newspaper headlines—had concluded that regulators too often made a hash of their job even when they chose to do it.

It's hard to think of an excuse for the SEC's failure to figure out what Bernard Madoff was up to in his massive Ponzi scheme, especially since at least one concerned individual, financial analyst Harry Markopolos, presented an analysis of the whole scheme to them on a silver platter years before Madoff himself confessed. But perhaps there's an explanation for the agency's apparent inability to act, one that dates back to the events of 2005 that culminated in the SEC's decision to fire Gary Aguirre.

Aguirre, a staff lawyer, had spent months investigating a series of mysterious trades by hedge fund Pequot Capital Management, and

believed that Pequot may have been tipped off to an upcoming merger by John Mack, then CEO of Credit Suisse and a friend of Pequot's founder, Art Samberg. (All the targets of Aguirre's investigation denied any wrongdoing and at first, the SEC dropped the matter without bringing any charges, although a second inquiry, begun in 2008, contributed to Samberg's decision to close his firm the next spring.)

Aguirre wanted to subpoena Mack, then in the running for the CEO's job at Morgan Stanley, to question him about his relationship with Pequot and obtain records of any conversations related to the merger in question. His superiors at the SEC told him to back off, pointing out that Mack had "juice" with top regulators; only months later, days before the end of his probationary period, the SEC fired Aguirre. A Senate investigation later concluded that both Pequot's trades and John Mack's actions were worthy of further investigation, as Aguirre had declared, and that there certainly was a "sufficient basis" for asking Mack some pointed questions under oath. The senators lambasted the SEC for its lack of backbone and particularly for paying "undue deference" to Mack, because of his role as a captain of Wall Street. Instead of seizing the opportunity to investigate the links between Wall Street and the hedge fund industry, the later report concluded, the SEC backed down. And, the senators added, when Aguirre tried to alert the SEC's top brass to the issue, the agency's internal investigators "failed to conduct a serious and credible investigation" of Aguirre's claims.

John Mack would ultimately testify—but the timing was unusual; he would discuss the trades only a few days after the statute of limitations for any potential offenses had lapsed. True, Pequot agreed to pay $28 million to settle charges of insider trading in the spring of 2010 (without admitting or denying any wrongdoing), but that occurred only after the financial crisis had pushed the SEC (under new leadership) to be more proactive. Only weeks after Pequot settled with the SEC, the SEC settled with Aguirre: the latter's wrongful termination lawsuit against the agency was ended with the payment to him of $775,000, representing his full salary since his termination as well as legal fees. In the immediate

aftermath of Aguirre's fruitless efforts to depose John Mack in 2005, followed by his firing only months later, it was clear to anyone still in doubt that trying to rein in Wall Street was likely to be more trouble than it was worth. If trying to put John Mack in the hot seat got Aguirre into hot water, why would any regulator trying to keep his job (or get a new, better-paying one on Wall Street later) pursue allegations about the equally powerful former chairman of the Nasdaq Stock Market, Bernard Madoff? It seemed tantamount to committing professional suicide.

That's the kind of message that the hands-off approach to regulation was sending, explicitly or implicitly, for much of the two decades leading up to the crisis. Regulators may have helped resolve the Long-Term Capital Management debacle, but they didn't help to prevent it. Analysts and short sellers were the first to publicly discuss their concerns about Enron's opaque accounting; a detailed SEC investigation followed, but as short seller Jim Chanos of Kynikos Associates said at the time, "It just gave us all the gory details; it wasn't as if they were catching anything or discovering anything that anyone who had looked at their financial statements didn't already suspect was there. It wasn't regulating and preventing a thing; it was coloring in the picture we already knew."[12] Regulators, Chanos points out, were bolting the barn door long after the horse had fled. Speaking out again in 2009, Chanos argued at the Intelligence Squared debate that "there has not been one major financial fraud in the past 25 years uncovered by the government, outside auditors, or outside counsel. It's always been journalists, whistle-blowers, or short-sellers, or some combination thereof."[13]

Ultimately, the combination of regulation and deregulation created a particularly toxic brand of chaos. In the aftermath of the near collapse of AIG, Congress and other onlookers went hunting for the regulator that should have been scrutinizing the doings at AIG's financial products division. (That London-based unit was the part of the insurance company earning the big fees selling credit default swaps and failing to maintain any capital against potential losses, bringing AIG and the financial system itself so close to collapse that by mid-2009 the government had forked over some

$170 billion to save AIG alone.) They found dozens of potential suspects; in every country where AIG did business—virtually every developed nation and many developing ones as well—there was a regulator responsible for overseeing part of their business. Then, on March 5, 2009, Scott Polakoff, the interim director of the Office of Thrift Supervision and heir to the chain-saw-wielding Gilleran, somewhat sheepishly asked to interrupt a Senate hearing into AIG's near demise to 'fess up. "It's time for OTS to raise their hand and say they have some responsibility and accountability here," Polakoff admitted. "We were deemed an acceptable regulator for both U.S. and domestic and international operations." Florida senator Mel Martinez seemed taken aback. "You [are] the regulator we've been looking for," he marveled. "I think we had assumed there wasn't one." "I'm the one," Polakoff responded. Anyone who had watched as one OTS-regulated institution after another collapsed as a result of poor risk controls might have been forgiven for whispering to himself, "I might have known."

Perverse Incentives

Without strong regulatory agencies in place—entities with the willingness to regulate prudently and the ability and resources to follow through and enforce their regulations—there was little incentive for financial institutions such as Washington Mutual, Countrywide, or AIG to maintain prudent provisions against future losses. The proverbial carrot—the lure of higher earnings—pushed them in the opposite direction, and there seemed now to be no effective stick in the shape of curmudgeonly regulators determined to make them do the right thing.

A 2004 report by the Office of Federal Housing Enterprise Oversight (OFHEO) disclosed significant accounting irregularities at Fannie Mae and Freddie Mac that couldn't fail to raise questions about the judgment of the CEOs of both agencies. Nonetheless, Franklin Raines, CEO of Fannie Mae, responded to a question from a congressman about whether the agency's decision to set aside a

mere 3 percent of its assets against possible future losses—a razor-thin cushion by most standards—by declaring that he felt it was actually too large a sum. The single- and multifamily home mortgages that Fannie Mae owned, Raines testified, were "so riskless that capital for holding them should be under 2 percent." While Raines didn't get any encouragement to slash those reserves further, his comments weren't met with howls of protest from anyone, from regulators to members of Congress. In fact, when Armando Falcon of the OFHEO testified about the accounting irregularities, Barney Frank of the House Financial Services Committee responded by saying, "I don't see anything in your report that raises safeness and soundness problems."[14]

Alan Greenspan, who had led the Federal Reserve for nearly two decades by this time, continued to believe that "enlightened self-interest" would cause Wall Street leaders such as Raines to act prudently. He cherished the illusion that their firms could regulate themselves, in the face of evidence showing him that enthusiastic risk taking was more integral to Wall Street than sober and attentive risk management. Sophisticated risk models and the even more elaborate derivative products from which Wall Street was earning more in profits (at higher profit margins) with every year that passed would do what they were designed to do, Greenspan was convinced. The only requirement was that the "enlightened self-interest of owners and managers of financial institutions [should lead] them to maintain a sufficient buffer against insolvency by actively monitoring their firms' capital and risk positions," he wrote a year after the collapse of Bear Stearns.[15]

Greenspan admits that he made a mistake. But rather than blame regulators for their failure to oversee what was going on, or the institutions for being imprudent, Greenspan directed his fire at the hypercomplex derivative products, which were "too much for even the most sophisticated market players to handle prudently." In other words, he said, there is nothing that any regulator or Wall Street rocket scientist could have done.

Greenspan may have been right, but the truth was that no one tried. Regulators didn't attempt to keep up with the pace of

innovation on Wall Street, the growth in its use of and reliance on leverage, and its growth in size and reach. Even had they wanted to rein in what was going on, their efforts would have been doomed to failure.

There's a good reason why Greenspan is now widely viewed (particularly on Main Street) as one of the chief culprits responsible for the financial crisis. As is the case with most regulators, his errors were ones of omission rather than commission, but they were big ones. If anyone had the ability to realize clearly that Wall Street was motivated more by greed and the fear of losing a fraction of a percentage point of market share to a rival rather than by the fear of being seen to be less than responsible or honorable custodians and users of the financial grid, it was Greenspan. It was he who clung to the conviction that a prolonged period of ultralow interest rates wouldn't harm the financial system, who believed dogmatically in the probity of the financial institutions and their ability to manage their business, who kept the punch flowing long after the partygoers were intoxicated and reeling around half senseless.

Greenspan, dubbed "the Maestro," was perhaps the single individual who had the gravitas and the power to stand up to Congress, the president, and Wall Street CEOs and warn them they were being reckless or shortsighted. Had he chosen to, he could have insisted that legislators transform the OTS into a powerful entity with the will and the ability to regulate the IndyMacs and AIGs. He could have sounded the alarm about inadequate reserves and risky derivatives, as a handful of respected financiers such as George Soros and Warren Buffett were already doing. (Buffett memorably and presciently described derivatives as "weapons of mass financial destruction.") Instead, Greenspan proclaimed in 2004, as the bubble was taking shape, "individual financial institutions [have] become less vulnerable to shocks," while the financial system as a whole was downright robust. And as for those derivatives, the ones that by 2009 he argued had been too much to handle? In 2003 he contended that they were an excellent device for transferring risk from those who couldn't handle it to those who

could. He suggested to the Senate Banking Committee that regulating them would be a mistake.

The derivatives market is perhaps the single largest example of deregulatory zeal on Wall Street. When the regulatory framework that still governed Wall Street in 2007 was created in the 1930s, no one dreamed that these products would even exist. (Getting a 1940s-era policy maker to plan for derivatives was about as rational as suggesting to a Victorian policeman that he send off blood traces found at the scene of a crime to be tested for DNA.) Like all financial innovations, derivatives were a compelling addition to the tools at Wall Street's disposal. A corporate treasurer could use interest rate swaps to manage his company's exposure to interest rates; currency-related derivatives enabled companies that earned a lot of income outside the United States to manage the risk associated with unexpected moves in the value of the dollar. Used that way, derivatives reduced risk for Wall Street's clients.

But these high-octane instruments could also be used as outright bets on the direction or movement of markets, creating more risk for their users. It all came down to how they were being employed. And during the 1980s and 1990s, as derivatives became far more widely used (data from the International Swaps and Derivatives Association, ISDA, showed a jump from about $850 billion in 1985 to $8.5 trillion by 1993), concern that regulators didn't have a clue about how they were being used began to mount. ISDA's membership—which included most of the big Wall Street institutions along with other large and midsized banks—successfully fought off a first effort by the Commodity Futures Trading Commission to bring derivatives under its oversight. By the mid-1990s, when market events pushed regulation back up to the top of the agenda once more, ISDA had helped the industry prepare to fight back. "Market discipline is the best form of discipline there is," Mark Brickell, then head of ISDA, was guaranteed to proclaim, in one way or another, at every ISDA-sponsored event.

But some of these highly structured products now were causing losses on Main Street and attracting the attention of both legislators and regulators. Procter & Gamble and Gibson Greetings were hit

with losses related to derivative-like instruments on their books that their treasurers insisted didn't perform as Wall Street had promised. (It remains up for debate whether the treasurers really didn't understand what they were being sold, or simply claimed not to when their bets later turned bad.) Meanwhile, Orange County had lost some $2 billion on leveraged bond derivatives called inverse floaters and in 1994 became the largest U.S. municipality to declare bankruptcy as a result. Its treasurer had bought the derivatives from Merrill Lynch after first trying to deal with J.P. Morgan. "Under no circumstances should we deal with this client!" concluded J.P. Morgan banker Bill Demchak, returning to New York after a meeting with the treasurer, Robert Citron, having realized just how clueless the bank's potential client was about what derivatives were, what they could and couldn't do, and the risks that were involved.[16]

Even before the losses, alarm bells were ringing. Richard Breeden, once known as an avid deregulator during his days at the helm of the SEC, warned corporate directors about the potential risks of derivatives in a Wall Street Journal editorial. In May 1994, the General Accounting Office (GAO) presented a 195-page report summarizing two years of study of the burgeoning derivatives market to Congress. The GAO—better known as a supporter of free markets than of regulation—concluded that there were "significant gaps and weaknesses" in the way that derivatives were regulated and urged Congress to appoint a federal agency to oversee "the safety and soundness of all major OTC derivatives dealers." A fierce fight followed in Congress and within the broader business community, with many regulators lining up alongside Wall Street, ISDA, and Greenspan. A handful of congressional leaders took up the regulatory battle. When in a hearing on proposed derivatives regulation ISDA's Brickell blasted Representative Jim Leach for treating derivatives differently from other securities, Leach retorted that they were different. They "are new, they are off balance sheet, they are a totally different dimension."[17]

Ultimately the free market fundamentalists prevailed, partly because some former critics saw the light. Gerald Corrigan, during

his days at the helm of the New York branch of the Federal Reserve—the Fed post that gives its holder the closest view of what is going on on Wall Street—had once voiced concern about the newfangled and complex securities. Upon leaving the Fed, Corrigan went to work at Goldman Sachs; soon he was named cochairman of the fledgling Derivatives Policy Group, whose goal was to convince legislators that the bankers themselves were in the best position to both understand these complex instruments and manage their risks. Wendy Gramm, a former CFTC chair (and wife of former senator Phil Gramm, coauthor of the legislation reversing the Depression-era Glass-Steagall Act; she would become infamous as a member of Enron's audit committee), suggested that Washington should "resist the urge … to over-regulate what we just do not understand."[18] Greenspan's confidence in free markets remained unshaken; he continued to assure Congress and the public throughout the 1990s that the market could regulate derivatives usage just as ably as any agency.

As the usage of derivatives continued to grow and spread throughout the financial system, with more and more complex iterations being devised, concern increasingly revolved around the lack of transparency in the market for these instruments. The existence of a stock exchange provides a degree of transparency that helps investors value a company's equity; the very liquid bond market, even in the absence of an exchange, made tracking bond prices relatively straightforward. An investor might quibble over whether the valuation the market was giving to the stocks or bonds was appropriate. But the transparency of the market meant that she could figure out what that valuation was with the click of a mouse.

In contrast, derivatives—which tend to be more customized instruments—don't trade anywhere and for decades didn't clear through any entity that was monitored by a regulator. Anyone requesting the most basic information on the industry—such as the notional value of credit default swaps written—could obtain only informed guesstimates. Brooksley Born, head of the Commodity Futures Trading Commission (CFTC) in the late 1990s, asked Wall Street and other interested parties to comment on ways that

derivatives might be regulated in order to be sure that these increasingly ubiquitous and high-octane instruments didn't threaten the stability of the financial system before regulators were even aware of what was going on.

Within the blink of an eye, the deregulatory gang circled the wagons and began heaping scorn on Born. Even the crisis surrounding Long-Term Capital Management, whose losses were caused in part by the hedge fund's use of derivatives to magnify its bets on the bond market that later went sour, failed to save Born's initiative—or her career. Congress barred the CFTC from wielding any regulatory clout over derivatives for six months; Born resigned in 1999. (Born would be back. In 2009 she received the John F. Kennedy Library Foundation's Profile in Courage Award, presented to the public servants who have made courageous decisions of conscience without regard for the personal or professional consequences, for her efforts to bring the derivatives market under some kind of regulatory oversight. She was also named a commissioner of the FCIC, putting her in a position to shape the debate surrounding future regulation and closely question her former adversaries.) The same year, Greenspan and others (including then Treasury secretary Bob Rubin, who would later become vice chairman at Citigroup, a major player in global derivatives markets) proposed that Congress ban the CFTC from any future meddling in the derivatives universe. It wasn't either necessary or desirable for Congress or anyone else to meddle with derivatives, Greenspan declared firmly on several occasions. All that was needed for the world of derivatives to function smoothly with minimal risk was for it to remain as unfettered as possible; the bankers wouldn't let it get out of hand.

Of course, like so many analyses—the Treasury's report on the shenanigans at the OTS, the UBS shareholders' report, and a chilling SEC survey of what went wrong at Bear Stearns—this chain of events looks more dramatic and alarming when viewed with the benefit of twenty-twenty hindsight. At the time, many Wall Street regulators believed the real threat was not lax regulation but overly oppressive regulation. Creating tough new derivatives rules

wouldn't wipe out the demand for these products overnight, and it certainly wouldn't eliminate the eagerness of the global investment banks to earn fees from structuring and selling them. The impact of regulating derivatives would have been to drive the business offshore and undermine Wall Street's preeminence as a financial center. With every year that passed, this became a more likely scenario, it seemed. In the wake of economic liberalization in China, new businesses were being formed at a rapid clip; the demand for capital was at its height there, and an Asian financial institution could conceivably use success in China to establish itself as the next Citigroup or JPMorgan Chase. Then there was Europe, where the city of London was making determined efforts to compete head-to-head with Wall Street for the title of global financial capital.

As late as 2005 and 2006, those fears seemed even more intense. In the wake of the billions of dollars lost amid the accounting scandals revealed at the beginning of the decade, Congress passed the Sarbanes-Oxley Act. Sarbox, as it is familiarly (but not affectionately) known, tried to address a valid concern: the fact that corporate managers had been able to manipulate their earnings and distort the portrayal of their financial position.

But Sarbox created a financial burden for the publicly traded companies that had to comply with the new law, particularly smaller companies. While the SEC had originally estimated the cost of meeting the new audit and governance rules at around $91,000 per firm, companies reported spending an average of $4.36 million each in 2004 alone, the first year that the rules took effect. Those figures were reported by the Committee on Capital Markets Regulation, which also noted that while half of all IPO proceeds raised in 2000 by companies (U.S. and foreign) selling stock occurred through a transaction on a U.S. exchange, by 2006 that had shrunk to only 5 percent. (It's unclear whether the reason was actually the competitiveness of American capital markets or other factors, such as the reality that a growing number of IPO candidates were non-U.S. companies that preferred to go public on an exchange based in their own country.) Meanwhile, the independent

group noted that private equity funds were growing rapidly, a clear signal that regulation and the costs of complying with regulation were keeping both issuers and investors out of the public markets—at least in the United States.[19] In London, however, the London Stock Exchange's Alternative Investment Market (AIM) was increasingly appealing even to U.S. companies that might have been expected to go public on Nasdaq; it held regular marketing seminars in New York and San Francisco to which were invited investment bankers and promising young private companies.

The London exchange bragged about AIM's "pragmatic and flexible approach to regulation" (which involves the company picking one of a number of approved lawyers, accountants, or other corporate finance professionals to vouch for its bona fides, permitting both the company and the exchange to outsource regulatory issues to these "nomads"). Alarmed by this and other trends (companies were also going public in Amsterdam and Tokyo; U.S. investment banks viewed China and even Europe as higher-growth markets), groups such as the Committee on Capital Markets Regulation increasingly spoke out about the oppressive burden that regulations like Sarbox created for Wall Street. "Let's be frank—people liked London because it was less regulated than New York," says the head of one of the large hedge funds that began building up a presence in the city at the beginning of the new millennium. "If you were a company going public, that was what mattered, period. For hedge funds, there was the extra benefit of the time zone." (From London, hedge funds could trade in Asian markets in the morning, European markets throughout their working day, and U.S. markets in the afternoon and evening.)

The SEC, meanwhile, became the target of a very specific and intensive lobbying effort to reduce the burdens of regulation on the part of Wall Street in the spring of 2004. The big investment banks, led by Goldman Sachs, wanted to increase the amount of leverage they could take onto the balance sheets of their brokerage divisions. If the SEC agreed, the investment banks could stop holding so much capital in reserve against future losses by their brokerage divisions. Instead, that capital could flow up the corporate chain to the parent

company, which could put it to work in ways best calculated to increase ROE and profits—ways that included investments in CDOs and mortgage-backed securities as well as credit derivatives and other complex structured products.

Since the net capital rule had been passed in 1975, investment banks had been required to limit the amount of leverage to $12 in debt for every $1 in equity on their books. They also had to tell regulators and shareholders if they approached that level too closely, and to stop trading if they exceeded it. In practice, that meant that leverage ratio rarely topped 10 to 1. But in a low-interest-rate environment, taking more risk and building up leverage levels was more vital for investment banks trying everything they could to pump up their return on equity. And the SEC seemed to feel that Wall Street was now grown-up enough not to require any adult supervision, that the investment banks were interested enough in their reputations and self-preservation not to do anything stupid. So, after a brief meeting in April 2004, the SEC, under its chairman Christopher Cox, gave the go-ahead to switching to a new monitoring system, one that allowed the firms themselves to establish their own capital levels based on their own computer models. "I keep my fingers crossed for the future," quipped SEC commissioner Roel Campos, voting in favor of the measure.

Indeed, the decision proved to be the equivalent of firing a starter's pistol. The race itself was between the major investment banks, each of which seemed to be eager to claim the title of being the first to pile the largest amount of leverage on its balance sheet —or at least to deploy leverage to maximize return on equity and profits. At Bear Stearns, leverage peaked at around $33 of debt for every $1 of equity, while at one point Merrill Lynch had leverage ratios of 40 to 1. Not surprisingly, the golden years of finance followed the repeal of these net capital laws: by 2006, financial services companies made up nearly a quarter of the U.S. stock market's capitalization, compared to about 15 percent over the previous decades, and those companies earned 43 percent of all the earnings reported by companies in the Standard & Poor's 500 index.

Ironically, the SEC was able publicly to spin this de facto bit of

deregulation as a way to increase its ability to keep an eye on what Wall Street was up to. That's because in exchange for the relaxation of the net capital rule, Wall Street firms agreed to let the SEC scrutinize their balance sheets, an agreement that conveniently dealt with another Wall Street headache—the threat by the European Union to regulate U.S. brokerage units doing business in England, France, and other parts of Europe. The EU authorities pledged not to do so if the SEC promised to regulate the parent entities. John Heine, the SEC spokesman, proclaimed that in fact the new 2004 rules "strengthened oversight of the securities markets, because prior to their adoption, there was no formal regulatory oversight" or liquidity standards for the parent holding company.[20]

That may have been true in theory, but in practice the SEC didn't seem terribly worried about what Wall Street was up to at either the brokerage firm level or the parent company level. Seven people were given the task of examining the finances of the parent companies. Performing that role, scrutinizing the balance sheets of the investment banking industry's largest players, should have given them enough insight into the levels of leverage and risk within the industry. However, they didn't act to rein in that risk taking, whether because they didn't believe it posed a systemic threat to Wall Street or because they lacked the power to address any problems that they spotted. (The contents of the SEC's postmortem on Bear Stearns, which not only clearly spelled out the firm's missteps but also suggested that regulators were aware of those missteps as they occurred, suggests that the latter explanation for inaction was more probable.[21]) Between March 2007, when the first questions were beginning to surface about the subprime crisis, and the autumn of 2008, after the collapse of both Bear Stearns and Lehman Brothers and the sale of Merrill Lynch to Bank of America, the group didn't even have a director to oversee their activities and lobby for action at higher levels within the agency.[22]

If Greenspan was correct in his suggestion that it was the nature of CDOs, derivatives, and other financial products that caused the problem, along with the way financial institutions failed to manage the risks they created, regulators should have admitted their

inability to control that risk. If the various regulatory bodies had simply acknowledged that they couldn't monitor Wall Street anymore, much less prevent investment banks from taking foolish risks, they would have delivered a clear message to legislators and investors alike that the latter would need to step up their own vigilance. Acknowledging that the regulatory system wasn't up to the task of reining in the increasingly complex world of Wall Street would have told other financial system participants to be still more prudent and protect themselves, since the regulators could no longer do it for them.

As it turned out, self-regulation remained the order of the day but ended up making no one happy. It irked Wall Street, which disliked having to pander (as bankers saw it) to regulators. In the eyes of Wall Streeters, most of these officials weren't nearly as smart as the financiers they were overseeing; certainly, investment bankers argued, they didn't understand what Wall Street's risk-taking culture was all about. After all, if the regulators were really competent and capable (or so the Reaganesque argument ran), they would have pursued a career on Wall Street itself, taking those risks and making big bucks, instead of becoming faceless bureaucrats. For their part, regulators were continually frustrated by their inability to get a clear picture of what was going on in the increasingly fragmented financial universe. Chaos seemed the most likely result of the potential information gap.

Most crucially, everyone seemed to want to defer to Wall Street. Politicians relied on Wall Street institutions for campaign donations; regulators such as the OTS relied on the same institutions to maintain their clout and budgetary power. Even today, it is Wall Streeters who have been chosen to oversee the bailout and restructuring plans by government officials.

At first blush, it seemed as if the credit rating agencies had a unique chance to speak their minds. They had acquired the status of quasi-regulatory institutions thanks to Depression-era rules banning banks from owning non-investment-grade bonds; that made agencies providing the now urgently required ratings a de facto part of the Wall Street regulatory apparatus. Ratings agencies didn't

report to Congress or rely on politicians for their budget needs. Ironically, as parts of the shadow banking system (such as securitization) became more important to Wall Street but also more likely to escape the oversight of other regulators, the ratings agencies became more crucial. At the same time, significantly, the nature of financial products became more complex. Only a triple-A rating could compensate for the complexity of the products emerging from the CDO-creation pipeline, enabling Wall Street to earn its fees and book the profits from its transactions.

Alas, the ratings agencies' ability to serve as some kind of guardian of the health of the financial system proved even more fallible than that of the accountants who had blithely overlooked years of financial misstatements by the likes of Enron and WorldCom. Part of the problem lay in the deceptive simplicity of the ratings themselves. The theory was that investors should be able to count on the credit quality of a triple-A asset to ensure that it would sail through any storm and emerge relatively unruffled, except perhaps in the event of a nuclear war or global pandemic. As bond managers liked to say, if a triple-A bond's quality deteriorated suddenly and significantly—enough, say, that it crossed into junk bond territory—then investors would have a hell of a lot more to worry about than what was happening to their portfolios. They'd be stocking up on canned goods and ammunition and heading for the hills. In contrast, a triple-B rating, while still investment-grade, signaled that an investor needed to monitor the transaction more closely. The ability to apply this very simple rating system to the extraordinarily complex world of structured finance was a coup for Wall Street, but it left investors with the perception that this new breed of security was just as easy for everyone to value and judge the risk of as a plain-vanilla bond.

The other problem was and remains the perennial one on Wall Street: the magnitude of the fees available for rating these CDOs and the identity of those footing the bill. Rating agencies may not have had to report to Congress, but they needed to report to their own shareholders. Turning down the opportunity to rate a CDO deal, a transaction that could generate $100,000 in fees for the agency,

would have been just as hard to explain to their own investors as the decision by an investment bank not to structure the potentially lucrative CDO package in the first place. Not surprisingly, given the growing importance of structured finance products that required ratings, the ratings agencies became more deferential to Wall Street institutions, working with them to tweak the design of the product in question. By 2005, about half of Moody's revenues came from the fees it earned for evaluating these and other structured products, and as much as 80 percent of its growth in revenue was coming from the same kinds of complex products. As the assets underlying the CDOs became more risky, the ratings agencies had become so dependent on fees they earned from them that turning down a deal became harder.

Marty Fridson, the veteran bond market analyst, says the real conflicts of interest didn't arise at the ratings agencies until recently, when they began to rate structured products such as CDOs. "For years, people objected in principle to the fact that the issuers selling the bonds paid the agencies for the rating, but in practice, it was rarely a problem," he argues. Information on the bond and the issuer's financial position was readily available to any analyst who wanted to check the accuracy of the agency's rating. And, Fridson points out, at the end of the day, a company that needs capital often has less clout than the rating agency. "The rating agency has an interest in maintaining the integrity of the rating; the issuer has to pay for that rating regardless of what it is, if they want to be able to sell the bonds."

In the world of structured finance, however, if the senior tranche of a CDO didn't get a triple-A rating, investors would be less likely to purchase it and the deal would be pulled. With no deal left to rate, fees could be as much as $500,000 for a straightforward CDO; $850,000 for something more complex, as the FCIC later reported. Multiplied by the growing number of transactions taking place at most major financial institutions on the Street, this was hardly chump change for the rating agencies. "The deal only worked if the top part could get a triple-A rating, and so it was in the agencies' interest to make sure they could do that," Fridson explains. The

balance of power tipped definitely in favor of Wall Street. "No triple-A rating, no deal. No deal, no fee. Even if they'd had all the good intentions in the world, it would have been hard for them to manage that big a conflict of interest," suggests Fridson. "Both sides had a vested interest in getting it right—at least, getting it to the point where it could be sold." After that, it was caveat emptor.

Anyone expecting Moody's to apply the brakes to the runaway train, however, had failed to recognize that some of the same considerations fueling Wall Street's addiction to risk taking were present among the rating agencies as well. In 1998, Moody's had become a publicly traded firm, meaning that its own outside shareholders could now also clamor for higher profitability. Mark Froeba, a former Moody's employee, told the FCIC that prior to that watershed event, "an analyst's worst fear was that we would contribute to the assignment of a rating that was wrong." Later, it became "that he would do something, or she, that would allow him or her to be singled out for jeopardizing Moody's market share." Indeed, Moody's employees reported that their decisions were tracked and second-guessed whenever a deal went to a rival such as Standard & Poor's. Sometimes, the hapless analyst would be told to justify any action that led to losing a deal in a written report to their superiors. Investment banks picked up on this hunger for fees, a hunger they were all too familiar with: analysts who proved too uncooperative or demanding would be told that their bosses would be informed that they were being "unhelpful." "They would threaten you all the time," former Moody's employee Gary Witt told the FCIC.

The hunger for deals may have encouraged the rating agencies to adopt many of the worst habits of the investment banks whose transactions they were—at least theoretically—monitoring. Why create a new, tougher model as mortgage underwriting standards fell? No one in the top echelons at the rating agencies wanted to find reasons to turn away business by offering less than a triple-A rating, and a new model might force them to do just that. Still, even a brief glimpse back through time should have been enough to force them to reconsider. Of all the structured deals put together

since 1980 and rated triple A on their debut, only slightly more than half were able to hang on to that rating for as long as five years, the FCIC discovered. It should have been clear that something was amiss with the initial rating process. And as for downgrades: well, that was a case of too little, too late. True, in 2008, rating agencies downgraded nine out of every ten CDOs in existence—but that happened long after the problems had become apparent and far too late for the downgrade to be the kind of useful "sell" signal to the investors that the rating agencies were supposed to be serving. Some of those investors—those who had scrutinized the rating agencies' processes as well as the deals—had sold by then; others would be caught owning assets that they couldn't sell for even pennies on the dollar.

No one in Washington or among the ranks of the quasi-regulators of the shadow banking system, it seemed, was both willing and able to oversee what was happening on Wall Street. To many, the debate over regulation felt increasingly academic, and little alarm was raised when an occasional regulator admitted that large parts of the financial system escaped not only the regulatory system's control but even its sight. In part, this was because of what Goldman Sachs strategist Abby Joseph Cohen once referred to (in the context of the dot-com years) as the "Cinderella economy"—nothing was ever carried to excess, and the level of market volatility remained low.

Initially, Ben Bernanke, Greenspan's successor as head of the Fed, was as phlegmatic as the Maestro himself. We were, Bernanke declared, living through "the Great Moderation," a period of market tranquility. As long as that lull continued, the gap between the regulators and their ability to monitor and oversee what was happening on Wall Street grew wider. Each Wall Street innovation ensured that the rules governing the Street became more outdated. Even the collapse of corporate giants Enron and WorldCom hadn't rattled confidence in the financial system for long. That financial markets could shake off such gigantic blows made even those worried about a looming subprime credit crisis confident that whatever happened, the financial system itself wouldn't suffer

lasting damage; therefore, the fact that regulatory rules were outdated and agencies underfunded was less troubling.

When the government did respond to crises with new regulations, these tended to be too ad hoc to serve as well-considered responses to the root causes of whatever debacle they were intended to address. Many of them had just as many unintended consequences as deregulation had had. The settlement between regulators and investment banks in the wake of the conflict-of-interest scandals in investment research on Wall Street (finalized in 2002) required firms such as Citigroup and Merrill Lynch to rigorously separate research from investment banking activities. That laudable objective led to research itself being starved of resources; now that analysts couldn't use honest and objective opinions to help make money for the institution (even when those opinions were their own, developed without reference to their institution's financial interests), they were no longer a profit center. That meant that promising analysts ended up working in other areas of finance.

The long-term consequences were damaging for both investors (who had access to less good-quality research on a wide range of stocks) and for smaller companies whose stock prices languished when investment banks cut back their research activities. There is certainly far less publicly available research on one of today's hot new market sectors, green technology, than there was on the Internet in its early days. Then came Sarbanes-Oxley, which imposed costly new burdens on entrepreneurial companies, and which was passed in a matter of days to address the kind of governance problems detected at Enron only months previously.

In the view of some market participants, the need for well-considered and thoughtful regulation of Wall Street risk taking was growing as markets became faster-moving (with trades taking place in milliseconds rather than mere seconds), more global (with the advent of twenty-four-hour-a-day trading), and more interlinked. "Look, we're not known, as a group, for loving regulation for regulation's sake," says the CEO of one large hedge fund. "But someone, somewhere, should have had some kind of oversight of what was going on with Wall Street's balance sheets. And yes, I was

saying so at the time. There should have been some risk-based guidelines on how big those balance sheets were allowed to grow."

On Main Street, there are lots of incentives for most of us to behave prudently. We try to keep some money set aside in cash for a rainy day—enough to cover our mortgage payment for a few months in case we lose our job or need to pay unexpected medical bills. In contrast, Wall Street seemed to be a kind of Wonderland, where normal rules of behavior were irrational. On Wall Street, all the incentives clearly urged financial institutions to believe that there would never be a rainy day and to behave accordingly. Washington succumbed to that way of thinking, whether it was due to Wall Street's lobbying (an appeal to legislators' self-interest) or to its preaching the virtues of self-regulation (an appeal to their idealism). By doing so, Washington seemed to suggest that this kind of magical thinking was just fine. As Niall Ferguson pointed out in the St. Patrick's Day debate, Washington-based institutions, from the SEC to the Fed, were great enablers of the hijinks on Wall Street. True, regulators didn't urge a financial institution to slash capital reserves to the bone—but they didn't protest when that happened. They even adjusted the rules, obligingly permitting the institution to do just that. Or, if the rules weren't changed, regulators such as the OTS quietly looked the other way.

Even after the collapse of Enron highlighted the risks associated with off-balance-sheet activities, Wall Street firms successfully lobbied for a rule that exempted them from consolidating their own offshore vehicles onto their publicly reported balance sheets. Suddenly, structured investment vehicles (SIVs) were being treated differently from off-balance-sheet vehicles at any other corporation. More and more, these SIVs became the place for financial institutions to park what they couldn't hold on their own balance sheets. While the SEC had relaxed rules pertaining to capital for the likes of Merrill Lynch, the Fed maintained tougher standards for the banks that it regulated. But neither the Fed nor any other regulator cared about SIVs, since they didn't show up on the balance sheet, and that balance sheet was what the regulators studied. So Citigroup shuffled lots of its hardest-to-manage securities into SIVs

it had created offshore; when outside investors in the short-term securities used to finance the SIV began to protest, Citigroup pledged to buy back those securities at their full value if they ever ran into trouble—a promise that would come back to haunt the firm in 2007 and 2008.

But Washington's failure to monitor the health of the money grid went beyond its lack of oversight over complex securities and offshore off-balance-sheet transactions. As well as providing too little oversight, Washington was providing far too much credit, thereby permitting and even encouraging the institutions whose well-being was crucial to the health of the financial system to pile on more and more risk.

The lower interest rates fell and the longer they stayed there, the more demand Wall Street found among its investment clients for higher-yielding securities, even those that came with extra risk attached. "The Fed did not take away the punch bowl [of easy money]," says economist Nouriel Roubini, the new generation's "Dr. Doom." Instead, he suggests, the Fed responded by adding "vodka, whiskey, gin and [other] toxic stuff to it."[23] And even as individual members of Congress tried to rein in some of Wall Street's excesses, they failed to realize how their enthusiastic participation in other initiatives was actually fueling them.

Certainly, few members of Congress objected to the principles enshrined in the series of laws they passed designed to encourage home ownership among all strata of American society. "We want everybody in America to own their own home," declared President George W. Bush in 2002 before launching yet another round of initiatives aimed at that end. And yet, as Sheila Bair noted in her FCIC testimony, "There are both opportunity costs and downside risks associated with these policies."

In the name of the overarching virtues of home ownership, subprime loans made their debut. These loans were more and more affordable thanks not only to the creative financing by financial institutions but also to rock-bottom interest rates being maintained by Washington even as the rate at which house prices grew each year suddenly jumped from 7 percent to 17 percent. Even after

Congress had become aware of the accounting problems at both Fannie Mae and Freddie Mac, they were slow to act to rein them in; by the time of their bailout, the two agencies had about $65 in debt for every $1 in assets. Those much-maligned subprime lenders could just claim that they were doing what their president commanded by turning more Americans into homeowners.

"Wall Street is one of the most competitive industries I have ever seen in my life," says Seth Merrin, founder of Liquidnet, who does business with nearly every major Wall Street institution. "If you put three or four of these guys in a room by themselves, within fifteen minutes they'll have some kind of bet going on, even if it's just how long it takes for a raindrop to hit the bottom of the window, and they'll all be yelling and screaming at their raindrop to move faster." These are the same people, Merrin wonders in disbelief, "that regulators expected to be rational and sensible and rein themselves in when the going got really exciting?" Merrin points out that the combination of government legislative policies that encouraged home ownership, fiscal policies that revolved around cheap money, and a deregulatory ethos was an environment designed to fuel ferocious competition between Wall Street institutions, each of which was intent on winning the biggest market share while maintaining the lowest possible capital reserves. "All the regulatory oversight catered to encouraging their self-interest, not to getting them to think about the fear part of fear and greed," he concludes.

The Fallout

Regulation is never perfect; every effort to shape the outcome of what Wall Street does leads to unintended consequences. Jeff Rubin, director of research at Birinyi Associates, a market analysis and investment firm, has studied the way markets work for decades and wonders, for instance, why regulators who oversee Wall Street have been so intent on pushing for ultra-high-speed transactions. "If an institution is investing for the long term, why does it make a

difference that the trader can complete the trade in fifteen seconds instead of thirty seconds, and do it in pennies rather than eighths [of a dollar]?" Studies he and others have done show that speed doesn't necessarily produce a better price, he says.

Rubin believes that many of the changes to the trading rules that have taken place over the last decade as markets have become more complex haven't benefited the entities for whose benefit Wall Street is supposed to exist—long-term investors and the companies who use Wall Street institutions to raise capital from that group of investors. "Those changes help Wall Street institutions like proprietary trading desks and hedge funds make money, not investors or issuers," Rubin declares bluntly. Regulators, he says, have been good at paying attention to the interests of the groups they are supposed to be overseeing but far less skilled at or interested in ensuring that the system their action and inaction produced was in the best interest of that core constituency.

Curiously, some of the beneficiaries of that lax regulation are now aligning themselves with Rubin (no relationship to Bob Rubin of Goldman Sachs, the Treasury Department, and Citigroup) and other critics. While no one has yet uttered the words "They made me do it!" some of the comments about regulators coming from senior figures on Wall Street don't fall far short of that. "Look, the people who were selling this stuff, they are being offered incentives to do it, in an environment where their bosses and the government knew, or could have known, what they were doing," says one top investment bank officer who worked closely with one of the former Wall Street CEOs dragged in to testify to Congress and the FCIC.

The executive is scornful of that process. "Oh, come on, it's for the TV cameras! It's like the car business; when the government is buying the car itself, why should I start worrying that this vehicle is unsafe at any speed? If Fannie and Freddie were buying these CDOs and subprime loans, if the regulators overseeing them and Congress weren't saying, 'Stop a second!' then even if at the back of your mind you say, 'Shit, I wouldn't buy this,' you justify it to yourself. It's your job to do this, you have bills to pay—and everyone, including the government, is telling you it's okay." At the back of

Wall Street's mind, the former banker admits, was the thought that as long as Washington was putting its stamp of approval on the whole housing boom, those financial institutions that helped keep it moving wouldn't be held accountable for their actions; they would have a kind of get-out-of-jail-free card. That reasoning would prove valid for some, if not for those at Bear Stearns and Lehman Brothers.

The hearings by Congress and the FCIC, designed to probe the causes and consequences of the mess on Wall Street, have been great street theater but offered little in the way of hope for the Street's critics. If anything, however, they have showcased what seems like a lack of knowledge among representatives and senators about how Wall Street works, its purpose, and the reasons it came so close to the brink of disaster. Those hearings and the myriad public debates on the causes of the crisis have also shown how ready each group—Washington and Wall Street—is to toss the burden of responsibility to the other. Some held higher hopes for the FCIC. After all, its membership was made up of financially sophisticated individuals who were very familiar with the ways of Wall Street, and several of its members were ready to ask pointed questions of those summoned before its public panels. But even had the final report not been hampered by the inability of the members to reach a nonpartisan consensus on the causes of the crisis, the report—which didn't appear until late January 2011—was far too late to influence the first and likely most significant piece of the reform legislation, the Dodd-Frank Act. At the time of writing, it remains to be seen whether the specific abuses and problems the FCIC panelists identified can be addressed by regulators as they try to implement the changes that Dodd-Frank requires.

Ultimately, both groups are culpable. After all, Washington didn't hold a gun to the head of Chuck Prince or any other investment bank CEO in order to force Wall Street to keep dancing. But regulators and legislators alike, instead of pulling the plug on the jukebox in order to preserve the health of the money grid, looked the other way and allowed the music to keep playing and Wall Street to keep boogying. In some cases, they took actions that

resulted in the volume moving higher and tempting more participants onto the dance floor. The regulators and their overseers in Congress and the White House knew—or should have known—that the nature of those on Wall Street would be to cavort enthusiastically until the last note sounded. They could have insisted that the band play a mournful pavane in order to change the atmosphere. They could have taken away the toxic punch bowl that Roubini describes in order to restore sobriety to the proceedings. At the very least, they could have confiscated the car keys of all the revelers, to ensure that the damage they caused was limited to a few smashed glasses.

When regulators did wake up from their long nap and act, it was too late. They opened the Fed's lending window, in time to rescue Goldman Sachs and Morgan Stanley but too late to save Bear Stearns. By forcing a last-ditch rescue of Bear in the shape of the JPMorgan Chase takeover and bailing out Fannie Mae and Freddie Mac, regulators sent the signal to Richard Fuld at Lehman Brothers and other Wall Street CEOs that bailouts might be available for them, too. Not until the last minute, during a series of marathon meetings over the course of a now famous and stressful weekend in mid-September 2008 at the fortress-like headquarters of the New York Fed, did it become clear just how dire the situation was.

Timothy Geithner, then head of the New York Fed, urged the assembled bankers to try to find a way to finance Lehman's toxic assets, a measure that would have averted a bankruptcy filing and facilitated the company's sale to Barclays or another acquirer as a going concern. The Wall Street senior bankers, summoned at the eleventh hour and fifty-ninth minute, balked. How costly would this bailout be? Certainly far pricier than Long-Term Capital Management had been, at a time when their own balance sheets were under pressure. And why should they help a competitor acquire Lehman? The bankers focused instead on finding a solution to prevent other investment banks from following Lehman down the drain; Geithner tried to refocus the discussion on the immediate problem of Lehman. "You guys have got to try harder," he demanded.[24] Ultimately, however, there was no alternative to

Lehman's collapse; the effort was too little, too late.

Should Washington's legislators and regulators have treated Wall Street the same way that parents of irresponsible teenagers treat their children—setting curfews and restricting access to the family car? Your answer to that question probably depends on the philosophical perspective from which you approach it. But in the wake of the financial crisis and the credit crunch that rippled throughout the broader economy, leaving mayhem in its wake, it has become nearly as difficult to suggest that Wall Street be left to regulate itself as it has always been for parents to let their teenagers follow their instincts, however destructive, in the name of a laissez-faire parenting philosophy. As George Soros—who himself has profited richly from free markets—suggests, "The stability of financial markets is not assured; it has to be actively maintained by authorities."[25]

What happens next is likely to follow the script written in the 1930s, in the wake of the last great systemic crisis. Washington is in the midst of rewriting the rule book according to which Wall Street must live, and building or rebuilding a set of institutions that can enforce those rules. Only when it's evident what form those new rules will assume—a process that may take another five years or more to become clear—will it be possible for Wall Street to move beyond the current range of interim responses and figure out how it will perform its core function for the rest of the twenty-first century.

In order to develop more than simply a Band-Aid solution, Washington and Wall Street will need to join forces and create a kind of accountable capitalism. Like it or not, Wall Street is not the type of business that can be allowed to simply collapse if its members behave foolishly and its investors don't rein them in. That means that somehow legislators and regulators will need to inculcate an awareness of that overarching duty among Wall Streeters, from the Lloyd Blankfeins right down to the greenest junior banker. Without a sense of fiduciary duty, on the part of both Wall Street and its overseers, to the financial system itself—and not just to those who earn short-term profits by participating in that system—there is little reason to be optimistic about Wall Street's

ability to avoid a future catastrophe.

Without free enterprise, there's no reason for Wall Street to exist, just as there's no reason to have cars if you don't have roadways on which to drive. But those roads have to be maintained, and cars have to be driven at safe speeds. Now it's up to a new generation of regulators and financiers to devise a new set of rules of the road for Wall Street, one that will emphasize its role as a utility.

PART III

THE NEW FACE OF WALL STREET

As fate would have it, two of the most illuminating comments on the nature of Wall Street, the reasons for the near-cataclysm and the prospects for its future, weren't made in any of the numerous hearings held by any of the Congressional committees and subcommittees or by the Financial Crisis Inquiry Commission. True, these summoned pundits of all kinds—regulators, legislators, members of the financial industry and academics—and provided them a forum within which they could debate the causes of the financial crisis and throw out their favorite ideas for reforming the system, to ensure that such a crisis could never be repeated. But while many of those trying to delve into what had gone amiss on the Street paid careful attention to these events and to the speeches given by the likes of Lloyd Blankfein and Henry Paulson to groups of all kinds, two throwaway remarks proved far more revelatory. Both were made by senior Wall Street figures—one to a radio talk show audience, the other in response to a question tossed out in the midst of a panel discussion held by financial journalists.

The first of these comments came from Richard Parsons, the lawyer who had previously served as CEO of the company formerly known as AOL Time Warner and who had been named chairman of Citigroup in early 2009. In May of that year, the government had taken a step toward restoring confidence in the financial system by requiring banks to undergo a stress test, running a crisislike scenario to see how well management coped and whether they had the financial strength to survive another liquidity crisis. Perhaps in order to celebrate the fact that the still-struggling Citigroup had passed the test (as had every other institution …), Parsons was a guest on a morning talk show on WNYC, the New York City affiliate of National Public Radio. He chatted amiably with the show's host, Brian Lehrer, about the results of the stress test and the future of New York as a global financial center, his soft, warm voice carrying a tone calculated to reassure and even soothe any Main Street residents listening who might still be fuming about the billions of dollars it had taken to keep Citigroup afloat, and the fact that the government had become the bank's single largest

shareholder.

Parsons's voice stayed calm as he made one of the most significant and revelatory statements about how Wall Street's legacy institutions—the behemoths like Citigroup that had survived the crisis, often with the help of massive injections of government capital—viewed the future. Citigroup, Parsons declared, was committed to weathering the storm. After that, he added almost casually, the bank would feel obliged to "do right by our two major constituencies." Seconds later, he unwittingly showed just how little those on Wall Street had changed their perception of the world and their place in it in light of the events of the last two years. Parsons didn't mention the government as one of those constituencies, or the taxpayers whose dollars had kept his institution afloat. Nor did he mention the financial system as a whole, on which we all rely to function smoothly. Not even the bank's clients—its depositors, borrowers, credit card holders, the companies for which its bankers helped raise capital—were acknowledged as one of those "major constituencies." These, the Citigroup chairman explained, "are our shareholders and our employees."[1]

In other words, the same kind of slavish catering to bonus-hungry employees and profit-hungry investors would come first and foremost on postcrash Wall Street—at least in the opinion of the chairman of one of its largest institutions. Parsons, via a spokesman for the bank, declined to elaborate on his comment or explain why this focus would produce better outcomes for the financial system and for shareholders than it had during the past decade, or why Citigroup would be better able to manage the kind of risks that single-minded approach created than it had been in all-too-recent memory.

John Mack, on the other hand, seemed to have emerged from the mayhem with a very different view of what went wrong—or, at least, a very different view of what was going to be possible on the new Wall Street. He disclosed this new attitude—one that surprised many who know Mack as a hard-driving banker ambitious to propel whichever institution he happens to be heading to the top of the league tables and to maximum levels of profitability—in

what appeared to be an unscripted comment in the midst of a panel convened by Bloomberg News and Vanity Fair to discuss media coverage of the crisis. Mack, weeks away from stepping down as CEO of Morgan Stanley, was in the audience; spotted, panel members urged him to answer a few questions. Soon the discussion shifted to how regulation of Wall Street needed to alter in order to prevent another such crisis in the future. Asked for his thoughts, Mack obliged. "We cannot control ourselves," he told a startled audience. Regulators have to do the job that Wall Streeters can't do for themselves: they "have to step in and control the Street." Mack declared he didn't care that ten or fifteen federal regulators now roamed the hallways at Morgan Stanley, now reborn as a federally regulated banking institution. "I love it," he said. "That kind of scrutiny forces firms to invest in risk management."

Two senior bankers, two events, two throwaway remarks—and two very different and conflicting pictures of Wall Street and the need for change. In Parsons's opinion—one that other bankers would later endorse, describing the crisis as nothing more than a particularly acute version of the kind of regular financial crisis that once happened every few decades—Wall Street could and should get back to business as usual as rapidly as possible. There was little need for change, Parsons implied. In contrast, Mack seemed to believe that without some kind of transformation in both the way Wall Street conceives its role and the way it does business, it might only be a matter of time until firms like Morgan Stanley would either precipitate or contribute to another financial crisis by focusing monomaniacally on what is in their own best interest and paying little heed to the kind of systemic risk their behavior creates.

Certainly, the rebound of the stock and bond markets beginning in the spring of 2009 and the rapid return to financial health of Wall Street's strongest survivors (Goldman Sachs reported profits of $13.4 billion in 2009; JPMorgan Chase would announce that its own earnings had more than doubled since 2008, hitting $11.7 billion) gave those Wall Streeters who had survived the carnage plenty to celebrate. As they enjoyed their bonuses—lavish, even if not quite back to precrash levels—Main Street erupted in outrage.

And the new administration of President Barack Obama took notice. In the early months of 2010, only weeks after the banks began reporting their financial results for 2009, President Obama announced plans for an overhaul of Wall Street. A key feature of this, he said, would be what rapidly became known as the "Volcker Rule," named after former Federal Reserve Chairman Paul Volcker, its architect. In future, the president said, deposit-taking financial institutions wouldn't be allowed to use their capital to treat themselves as their own best customers. No more proprietary trading; no more investing in hedge funds; no more participating in private equity investments as an investor.

The president didn't use the word utility in his bombshell announcement, but he may as well have done so. Only days earlier, investment analysts had voiced excitement about the future earnings potential of the biggest or most powerful Wall Street players—Goldman Sachs and JPMorgan Chase—suddenly switched their focus to calculating how big a hit those institutions would take to their bottom lines if they were forced to act solely as intermediaries and restrained from the lucrative businesses that had generated so much of their income in recent years. Goldman, they calculated, would feel the biggest hit, forfeiting an estimated $4.67 billion of earnings in 2011 if the president's proposals became law.[2] No wonder the squawks of outrage were heard from every corner office on Wall Street, as one CEO after another scrambled to make the case that proprietary trading, hedge funds, and private equity dealmaking hadn't been the cause of the financial crisis.

What Wall Street chose to overlook was the fact that those activities were symptomatic of the real problem. John Mack was absolutely correct in his diagnosis: left to their own devices, Wall Street firms cannot help themselves. They will revert to any and all activities that are in their own best interest, seeking out ways to earn higher returns and recruit the talent able to generate those returns by paying the most lavish bonuses and offering the most lavish perks. Risk management, however, would be seen in the same light as before: not just unprofitable, but eating into profits that otherwise could be paid out to either employees or

shareholders. The last crisis may not have been caused by proprietary trading, but by the attitude on Wall Street that had led to proprietary trading desks, prime brokerages, and "sponsor" groups becoming such powerful players simply because they could generate outsize profits symbolized what was wrong with the system. As long as Wall Street continued to reward itself so lavishly at the same time as it chose to view some of its clients as little more than "counterparties" that should be prepared to look out for themselves in any and all situations, the risk of a repeat of the events of 2007 and 2008 remained high.

The crisis had not—and still has not—reshaped the fundamental attitudes of many of Wall Street's leaders toward the financial systems. While they are responsible for making the money grid work efficiently and safely in the interests of all its beneficiaries, not just themselves or those able to reward them most richly, too many of the leaders think like Parsons: that their responsibility is to their shareholders and their employees. That attitude, coupled with the eagerness of Wall Street to return as rapidly as possible to the status quo ante once the immediate crisis had been averted, served as the catalyst for the president's reform proposals. "My resolve to reform the system is only strengthened when I see a return to old practices," Obama said at the time he proposed the "Volcker Rule."

Just because Wall Street's biggest institutions can construct CDOs and CDO-squared structures, because they can boost leverage levels, because they can structure transactions that even some of their bankers view as risky or dangerous for the investors that the investment banks convince to take the other side of the deal, doesn't mean that they should do so. And that's the problem at the heart of any discussion about the future of Wall Street: there are still too few incentives to say "no" to deals and financial products that shouldn't happen. True, the subprime lending market is largely moribund; financial institutions won't be able to take on nearly as much leverage under new rules set in place by national regulators and transnational groups like the G-20. The products that trigger the next bubble—and the next crash—won't be CDOs, junk bonds, or dot-com stocks. But as long as some players in the financial

markets—perhaps hedge funds, perhaps private equity funds, perhaps some other entities that aren't on our radar screens today in the same way that subprime lenders weren't a factor on Wall Street as recently as the mid-1990s—generate massive amounts of fees for Wall Street institutions and want to undertake high-risk deals, there will be little motivation for those intermediaries to just say no. On the contrary, there will be every reason to go along, because the financial rewards will be there—as will the sense that if they don't grab the opportunity, their rival will. Inevitably, as John Mack realized, financial institutions are programmed to seek out and emphasize the riskiest businesses because that's where the biggest profits can be made. Self-control is simply not part of Wall Street's DNA.

In a pinch, we can muddle along with a dysfunctional health-care system, or even an educational system that isn't doing justice to our country's children. But we can't exist without a robust financial system. The question becomes, what kind of corporate structures, regulation and policy frameworks will encourage Wall Street institutions to behave in the interests of all its stakeholders and in a way that doesn't jeopardize the health of the financial system itself?

The efforts at reform that we've seen to date, many of which I'll address in the remaining chapters, are only a partial solution. The conundrum can't be addressed unless and until we're prepared to start thinking of and treating Wall Street as the utility that it really is. That doesn't mean that its institutions must be government-controlled monopolies—far from it. On the contrary, just as a freewheeling Wall Street turning out subprime CDOs with reckless abandon proved dangerous, I'd suggest that a government-administered financial institution that dutifully loaned more to struggling businesses would be equally hazardous. True, helping a small business obtain a much-needed loan to stay afloat may be more altruistic than creating another subprime CDO just in order to capture the fees, but that doesn't mean it makes more business sense or is less risky. Nor does it mean that Wall Street institutions must accept a regulated rate of return set by the Fed or some other agency, or even limit the size of the bonuses they pay out to their

top-performing employees.

Rather, it means that everyone whose fortunes are tied to Wall Street—from the loftiest banker to the lowliest trader and including investors in firms like Goldman Sachs—must accept that the sole purpose of the financial system isn't to enrich them. To earn those big bonuses, they can't focus obsessively only on capturing outsize profits or on beating Goldman Sachs in the race to maximize return on equity or dominate the investment banking league tables. We must redefine the meaning of success on Wall Street to include more than just profits for Wall Streeters themselves, but reasonable outcomes for those who rely on it: access to capital, a transparent system, and bankers who treat them as valued clients and not simply disposable counterparties. The mantra "caveat emptor" is no way to run a utility.

In the chapters that conclude this book, I'll explore some of the ways the trauma of the financial crisis has already begun to reshape the world of Wall Street. Some firms have vanished; new players are emerging. There's a possibility that entirely new types of players could begin providing intermediary-type services. A quarter-century from now, the list of Wall Street's most powerful firms and individuals may be very different in nature as some of these changes upset the balance of power. Goldman Sachs may no longer be the firm everyone wants to mimic and to outperform. But without some kind of sweeping change, begun either outside or within the financial system, the Street's participants will always be chasing their most successful rival, whatever that firm happens to be. And that ethos is a damaging one, something we can't afford to retain as the "new" Wall Street emerges.

Yes, the Dodd-Frank Act has been passed; the FCIC has rendered its verdict on the causes of the financial crisis. But we're still in the early stages of seeing that new Wall Street take shape, and it's up to all parties concerned to ensure that the system that results is one that serves all their interests, from Goldman Sachs right down to the smallest client of the money grid. The ethos of "chasing Goldman Sachs"—pursuing the maximum level of profits and return on equity, without heed to systemic risk or the interests of all the

stakeholders in the money grid—is a model that must be abandoned in the name of creating a stable and sustainable money grid. Being a winner on Wall Street must mean being more than the firm that manipulates the grid the most successfully, earning the biggest profits in the process because that is all its own shareholders care about. After all, shareholders of the energy giant BP realized in the aftermath of the offshore drilling catastrophe in the Gulf of Mexico in the spring and summer of 2010 that the pursuit of profits wasn't all that mattered. What counted more, it turned out, was maximizing financial returns safely and with an eye toward the environmental consequences of its actions. The same is true of Wall Street, still grappling with the aftermath of its own version of a toxic spill. Perhaps one day it will rediscover and subscribe once more to Jack Morgan's pledge of doing "first-class business in a first-class way."

CHAPTER 8

Wanted: A New Model for Wall Street

Without question, 2010 was an "annus horribilus" for all those at Goldman Sachs. Admittedly, it had begun on an upbeat note, champagne corks popping to celebrate not only the firm's survival but also its startlingly rapid return to profitability in 2009. Even the professional pundits, the investment analysts who scrutinized Goldman Sachs's financial reports in an effort to predict just how well it would do, fell well short of reality in their forecasts. The firm was once again the envy of the rest of Wall Street, reporting $13.39 billion in profits, or $8.20 a share, compared to consensus estimates of $5.19 per share.

But the jubilation wouldn't last long. Even as the analysts were digesting the fine print of the year-end report and revising their earnings estimates upward for 2010, a series of blows began raining down on Goldman Sachs. Until that year, Goldman had seemed immune to the kinds of turbulence that sent its rivals scurrying for cover, while its blue-chip bankers seemed never to make the kind of missteps that caused those rivals to founder. Then came the news that President Obama's planned Wall Street reforms seemed likely to wreak havoc on the kinds of lucrative business that Goldman Sachs dominated and that generated a large proportion of those enviable profits it had just posted. Only weeks later came another, more serious blow: news that a newly ferocious Securities and Exchange Commission had sued the firm. Goldman Sachs, SEC enforcement officials alleged, had deceived its clients in the Abacus CDO transaction by concealing from them the role that John Paulson—the hedge fund manager who was eager to bet against the subprime mortgage securities in the transaction—played in selecting

the specific holdings in the deal. Had investors known that Goldman was bending over backward to cater to Paulson, would they have been as willing to buy in to the deal? The SEC's enforcement division thought not. Goldman's failure to disclose those facts—facts the SEC deemed "material"—rose to the level of fraud, the SEC alleged in its April lawsuit.

The envy of all his Wall Street peers until now, Lloyd Blankfein must have felt like the loneliest man alive at the end of the month as he sat in the hot seat in a Senate hearing room, struggling to explain to his Congressional inquisitors—members of the Senate's Permanent Subcommittee on Investigations—just why he didn't believe that his firm had an obligation to inform clients that it was trying to persuade to invest in subprime CDOs that its own bankers and risk managers were internally referring to the deals as lemons and the transactions as "shitty" or "crap." "Clients don't care about our views," he declared. For the first time in recent memory, Goldman Sachs's name and reputation commanded no respect or deference on the part of the senators; instead, they used the marathon session to challenge Blankfein and some of his senior officials on the basic principles of their business. Sometimes, they hit the nail squarely on the head, as when the junior senator from Montana, Jon Tester, demanded of the Goldman Sachs team assembled in front of him: "Who do you consider yourselves working for—the client or the firm?" That was just one of many questions that the Goldman team battled to avoid answering. "That's a complicated question," replied Dan Sparks, the former head of Goldman's mortgage business.

It didn't take too long for Goldman Sachs to realize that trying to convince the public, members of Congress, and regulators that its actions—selling what one Goldman exec described as "big old lemons" of mortgage securities into deals that could be peddled to its clients, or rather, its counterparties—were acceptable behavior was doomed to failure. True, the firm remained as resolute as ever in public: it had done nothing wrong; it had discharged all its obligations to its counterparty in the Abacus transaction. But even if the firm won battles along the way, a growing number of Goldman

insiders was convinced that it couldn't win the war: it had to settle the case in order to appease its clients, stop the run on its stock that had wiped billions of dollars of market value from its shares in the weeks that had elapsed since the case was filed, and move on to more important issues, like figuring out how it would make money in a new regulatory and market environment.

Already, the lawsuit had overshadowed Goldman's release of another quarter's worth of blockbuster earnings in April; none of the Goldman partners who assembled in June for the firm's annual jamboree wanted to have that state of affairs continue. Sure enough, by July the warring parties had reached a truce of sorts: while Goldman wouldn't acknowledge wrongdoing, much less fraud, it would admit that its disclosure standards weren't all that they could be and the firm would pay a $550 million fine to resolve the case. More significantly, the firm announced that it was already in the midst of a systematic review of its business practices—a tacit admission that these had drifted away from the principles of "long-term greed" espoused by the likes of previous generations of Goldman Sachs leaders. "There was a sense among us all that something, somehow had gone awry and needed to be fixed," says one former Goldman Sachs partner. "The consensus was that we needed to find the path back to the kind of business culture that we had had before; the kind of environment in which it would never have been conceivable for us to sell securities to our clients that we were privately describing as toxic, as lemons, as crap." Goldman Sachs had gone from being Wall Street's most admired and most envied firm to being its most reviled. True, rivals might still covet its profits, but now the sources of those earnings were coming under attack. Goldman couldn't afford to be perceived as the firm that was willing to do deals that a second-tier firm like Bear Stearns—an investment bank that hadn't been able to manage its own risk well enough to ensure its survival!—had turned down for ethical reasons.

But that left everyone with some big questions to address. What would the new Goldman Sachs look like? And would it be the kind of firm that could continue to dominate Wall Street and earn

outsize returns for its investors? Or was the Goldman Sachs era at an end? Would the new rules of the road being drafted in Washington favor new kinds of financial businesses? Would new players try to take advantage of the uncertainty? Would the financial crisis of 2008 and its fallout mark the end of an era or trigger little more than cosmetic changes to the way Wall Street did business? President Obama's objective was clear: he wanted an end to a financial system that had taken "huge, reckless risks in pursuit of quick profits and massive bonuses." But if the old Wall Street was mad, bad, and dangerous to navigate, what kind of new landscape would or should replace it?

Goldman Goes Back to the Drawing Board

Goldman Sachs had spent decades scrambling to become an elite institution and by the 1980s, it had more than achieved that objective. Now, despite everything that had gone wrong, the firm's leaders weren't going to sit around and wait meekly to be told what to do next by a passel of Washington bureaucrats. After all, Goldman bankers were known not just for their aggression but their vision: hadn't their risk management team succeeded in identifying the risks in the credit bubble and acted to prevent the firm's collapse, while wannabe Goldmans had failed? The fact that that very prescience was being held against them in the Abacus case was, in the eyes of those at Goldman Sachs, at least, downright bizarre, but it also signaled that it was time to go back to the drawing board and start reinventing Goldman Sachs before the regulators did it for them.

"It was kind of a crisis for everyone who had worked at Goldman during the big transition, during the time period where we had gone from being a firm that saw a value in principles to one that saw the greatest value in earning the fattest fees possible," says one former partner. Everyone wanted to recapture something of the spirit of the old Goldman Sachs—not the firm that the rest of the world despised because it was believed that Goldman had been

making money at the expense of all the other participants in the financial system while the latter foundered, but the business model that earned outsize profits by being more agile and nimble than anyone else when it came to navigating financial markets and earning an outsize share of the rewards that were there to be captured. "If the firm is going to be what it was, we need to find a way back to the days when 'long-term greed' was what mattered," says the former Goldman partner. "No banker can ever write e-mails like Fabrice Tourre did, showing how cynical he was about what the bank was doing, because there shouldn't be anything to be cynical about." It's not a matter of morality, he adds. "It's just common sense—it's prudence, it's responsibility, it's about all the other things that have gone by the wayside across Wall Street in the last decade or so."

That kind of thinking and the hope of restoring Goldman Sachs to its pinnacle atop Wall Street lay behind the review of business practices that Goldman began in the spring of 2010, while the review—with the implicit promise that Goldman had seen the light and would change its ways—helped to save the firm from the full wrath of the SEC and an even larger fine in the Abacus case. It also contained some unpleasant surprises for Goldman insiders. Particularly dismaying were the results of an independent survey of Goldman's clients, which revealed that many of them had become wary of the investment bank in recent years. To those who were still trying to convince themselves that Goldman had done nothing to violate clients' trust or that could be perceived as doing so, the results were horrifying: too often, a large number of clients said (after being promised anonymity) the investment bank put too much importance on its own interests at the expense of those of the clients. Insiders say they were taken aback by the magnitude and extent of the mistrust and skepticism and that the early survey results were among the factors that convinced Lloyd Blankfein to settle the SEC lawsuit as rapidly as possible. "Just imagine us asking a client to testify on our behalf in that kind of case, and then the dude getting up on a witness stand and saying nope, under oath, I can't swear that there's any reality to the Goldman mystique," says

one Goldman Sachs insider. “That scared the hell out of everyone in the corner office.”

If the Abacus deal symbolized and highlighted what Goldman Sachs and the rest of Wall Street had become—entities that served themselves first to the choicest dishes on the menu and leaving the leftovers for their clients—the business practices review was an opportunity to correct that, at least in the eyes of some of Goldman’s veterans who recalled the days when the investment bank was still a partnership and when there were some deals and some business relationships that the firm shunned as unprincipled, however lucrative they might become. “We just didn’t do every deal—that’s how we got that elite reputation in the first place,” says one Goldman Sachs alumnus. He and others applauded when, in January 2011, the results of the review once again enshrining client interests as paramount were unveiled. “Our experience shows that if we serve our clients well, our own success will follow,” the review declared. The second principle, that the firm’s assets are its people, capital, and reputation, was also a familiar one, albeit with a new twist in recognition of recent events: the review noted that the last of these—reputation—would be the most difficult to restore if it was damaged. Going forward, Goldman pledged, “prior to accepting a role with a client, we will exercise care to ensure that we are able to fulfill our responsibilities to that client. Having assumed a role, we will not undertake activities or accept a new mandate that would prevent us fulfilling those responsibilities.” Providing superior returns to its shareholders ranked third on this list of revised priorities.

But will this mean that Goldman Sachs actually changes the way that it does business, and help shape a new Wall Street? It’s hard to say. While Goldman promises to make its financial statements more “transparent” and easy to understand, it hasn’t laid out a plan of action: it’s still unclear whether or how Goldman will act on these principles in the future. It’s also hard to see how the bank will be able to keep the demands of shareholders for superior returns at number three on that list: after all, Goldman, like other publicly traded corporations, has a fiduciary duty to maximize shareholder

returns. All that matters is that the actions it takes to do so don't put the corporation's survival and well-being at risk. Will shareholders stick around if they believe Goldman Sachs is bending over backward to cater to its clients at their expense—if Goldman walks away from potentially profitable transactions?

Goldman Sachs, like other firms on Wall Street, had lost its way during the previous decade or two. A new kind of business model had evolved, one that led to investment banks establishing a hierarchy of clients, with the so-called dumb money at the bottom. That included, as the Senate and FCIC hearings made clear, institutions like the German bank IKB, which bought the Abacus securities from Goldman Sachs without knowing of John Paulson's full role in the transaction—and without, as Goldman bankers scornfully noted behind the scenes, doing enough due diligence to detect the degree of risk they were taking on in the transaction. (IKB's losses on this and other mortgage-backed securities investments made it one of the first banks to fail in the crisis; bailing it out required a cash infusion of $13 billion by a group of state-owned German banks.) "It's fair to say that the review caused us to think about the missteps we had made," says one Goldmanite. And yet, the review also seemed to duck away from some of the most critical questions. When it came to the issue of conflict of interest—who is Goldman Sachs putting first?—the firm took refuge in weasel words. Conflict of interest, it declared, "does not have a universally accepted meaning."

As Goldman's annus horribilus drew to a close and 2011 dawned, the only certainties were the questions that surrounded the firm and Wall Street as a whole. And the transaction that Goldman Sachs had hoped would give it a new public image—a $1.5 billion capital infusion into one of the most-watched companies of the last few years, the still privately held social networking site Facebook—was supposed to provide the world with evidence that a new, kinder, gentler Goldman Sachs was already taking shape. Goldman Sachs itself wouldn't be the primary beneficiary of the Facebook investment—the kind of pre-IPO financing that historically has paid off with hundred-fold returns in the case of similarly iconic

companies in the past, from Google back to Yahoo! and eBay. Instead, while Goldman Sachs, alongside a Russian investment company, would invest $500 million in Facebook, the bank's real role was the classic one of intermediary: it was responsible for negotiating the terms and conditions of the investment, which would include another $1.5 billion of capital from Goldman's private banking clients. "This is Goldman doing what it does best, adapting to new circumstances and finding a way to make them profitable," says Clayton Rose, a former banker now teaching finance to students at Harvard Business School. Instead of using the firm's own capital to capture all of the potential return, Goldman Sachs, it seemed, had found a way to use its capital to develop a business relationship. "Friending" Facebook earned Goldman Sachs a fee today, a relationship with the company that hopefully would put the bank in the pole position when the race to become lead underwriter for Facebook's IPO got under way, and it would make the affluent clients of Goldman's private wealth management business happy, too, as they'd get a unique opportunity to invest in Facebook, a deal they could brag about today and profit from in the coming years.

In postcrisis Wall Street, this was a sweet deal indeed, one that showed Goldman Sachs at its innovative best. Goldman, like other Wall Street players, needed to identify some clever new ways to make money, with some of their most profitable businesses under attack: if regulators and legislators had their way, there would be no more proprietary trading or hedge fund investments permitted, and even the practice known as marketmaking—which could mean holding positions on a bank's balance sheet for months, making it look uncannily like proprietary trading in the eyes of those predisposed to be critical—was under siege. Add that to the fact that new rules meant keeping higher levels of capital in reserve and using less leverage, and the prospects that firms would resume posting record profits were becoming dimmer by the day. Even the financial markets weren't cooperating. By the summer of 2010, trading volumes across Wall Street had become "painfully slow," as Richard Handler, CEO of Jefferies & Company, complained when

warning investors that the investment bank would post disappointing third-quarter earnings; a growing risk aversion and directionless markets, combined with uncertainty about everything from the global economy to the stability of the financial system, were keeping investors on the sidelines. Even venture capital funds weren't eagerly pushing forward more than a select handful of social networking companies with familiar brand names as IPO candidates for Wall Street's consideration. "It's far easier for us to get these companies acquired for a modest premium, and collect our fees for that, than it is to gamble that one of them might actually get investors excited enough to be worth our time and effort in pushing an IPO through the pipeline," said one banker who works extensively with Silicon Valley startups.

In that climate, the Facebook deal looked like a dream come true, especially as the orders came flooding in—more than $7 billion of them for the $1.5 billion of stock on offer. Then Goldman's success once again became its undoing. Because the deal was being orchestrated by the now notorious bank, and being done for a high-profile firm like Facebook, news of the private placement leaked out into the public domain, along with speculation that Goldman Sachs had reserved the right to hedge its own Facebook holdings, something not available to its clients. Goldman officials denied that, but they couldn't stop the flood of publicity—publicity that isn't permitted as part of a private placement sold to individual investors under the securities laws. The only prudent course of action was to pull back; only non-U.S. private banking clients would be allowed to participate. Goldman's bankers were furious, and so were many of those bankers' wealthy clients who were now shut out of what promised to be one of the most attractive deals of the decade.

The Facebook deal offers hope for Goldman Sachs, at least—hope that it will be able to find new ways to compete and thrive in the new, postcrisis Wall Street. "Firms that previously lived off highly customized transactions that have a high degree of intellectual capital involved, like Goldman Sachs and JPMorgan Chase, will find their businesses and profit margins under serious threat, based

on the way that the new Wall Street is taking shape," argued Rose in early 2011. "They will have to replace those earning with more traditional kinds of revenues, which also tend to have lower profit margins, so that's going to be a real challenge. The business models will have to change." And once again, a premium will be placed on creativity and innovation.

Reinventing Wall Street

In the aftermath of the crisis, and lingering on into early 2011, there were more questions about what the new Wall Street would look like than there were answers. The passage of the financial reform bill known as the Dodd-Frank Act in the summer of 2010 provides a context in which to pose those questions, but this significant package of legislation needs to be implemented and then face legal challenges that will further define what it does and doesn't permit Wall Street to do, before we will begin to understand the full ramifications of the new rules. Some lawyers calculate that will take five years or so; others argue it will be at least a decade.

In the meantime, however, Wall Street has already begun to undergo its own transformation, slowly and almost imperceptibly. Legislative reform and lavish bonus packages may have grabbed headlines throughout 2009 and into 2010, but other forces were already at work. Just as the bankers at Goldman Sachs were pondering what kinds of new transactions might make them money in this new business environment and laying the groundwork for the Facebook deal, even as the firm's leaders battled to put to rest the SEC lawsuit, across Wall Street other firms were asking themselves the same big questions: What does Wall Street do, and what should it do? How does it function, and how should it function? The magnitude of the crisis and the dislocation it produced had been so great that almost anything now seems possible, at least in theory. For the first time in some seventy-five years, since the changes to the financial system that came on the heels of the 1929 crash, Wall Street players have received a glimpse

of entirely new vistas and possibilities. It's almost as if they have just arrived in the Wild West, been shown a map on which all the territory is up for grabs, and been told to go out and stake a claim. Everyone, from the newest member of the tiniest regional brokerage to the most eminent Wall Street veteran, is free to take part in the game of reinventing Wall Street.

Even if angry and aggressive legislators and newly reinvigorated regulators impose new constraints on what some financial system participants can do, many Wall Street veterans still see more opportunity than risk. In some cases, those opportunities may influence how we redefine what Wall Street is and how it functions. Winners can come from anywhere. They can be found among the ranks of the giant financial institutions (including Goldman Sachs); the boutique institutions launched by star bankers that try to replicate what Goldman was two or three decades ago and thus repeat its successful transformation into an elite and astonishingly profitable institution; and even among the midmarket players that end up dominating one particular niche within the investment banking universe, whether it's health care or green energy. At least one giant hedge fund dreams of a future in which it joins the ranks of the intermediaries, becoming an investment bank in its own right as well as an investment firm. Why not?

Some of these businesses dream of becoming the next Goldman Sachs; meanwhile, the actual Goldman Sachs and its peers at the top of the Wall Street power structure are intent on modifying their own business models as much as they need to in order to take advantage of new opportunities and avoid fresh risks, all the while trying to prevent too much change of a kind that might topple them from their perch. "They will fight—ferociously—to recapture any ground that was lost during the storm," says Jimmy Dunne of Sandler O'Neill. "We have a window of opportunity, yes, but it will close, and we'll have to fight just as hard to hang on to whatever we gain."

In place of the magical thinking that dominated Wall Street in the years leading up to the crisis arose a kind of willful amnesia. Surely, leaders of the large legacy institutions like Goldman and

JPMorgan Chase reasoned, the events of 2007 and 2008 were nothing more than a giant nightmare from which they were now awakening? At first, events conspired to support that perspective. Goldman Sachs, whose employees seemed able to spin straw into gold, reported the largest quarterly profit in its history in the summer of 2009, only weeks after repaying $10 billion of government bailout money. By the end of the third quarter of 2009, Goldman and JPMorgan Chase were running neck and neck in the profitability sweepstakes, each having posted profits of around $8 billion.

Of all the firms fighting to reclaim their previous power and prestige, Goldman, as already discussed, had the steepest uphill climb. As its coffers swelled with its fresh profits and employees began spending their bonus checks, populist fury mounted. Even charitable donations didn't help. The level of outrage was reflected in the tone and content of Matt Taibbi's scathing profile of Goldman published in the July 2009 edition of Rolling Stone. Rehashing every conspiracy theory surrounding Goldman, Taibbi concludes (in some of the most memorable prose ever crafted in a work of business journalism) that Goldman is "a great vampire squid, wrapped around the face of humanity, relentlessly jamming its blood funnel into anything that smells like money."[1]

Lloyd Blankfein, embarking on a PR crusade to stem the hostility, didn't help matters. Granting an interview to the Times of London, Blankfein tried to emphasize Goldman's crucial role in the financial grid, arguing "we help companies to grow by helping them to raise capital. Companies that grow create wealth. This, in turn, allows people to have jobs that create more growth and more wealth. It's a virtuous cycle." But then, he went on to declare that Goldman Sachs is "very important" and that it serves a "social purpose." Blankfein even told the interviewer that he believes he is "doing God's work."[2] His performance during the Senate hearings, during which he was interrogated on the details of the Abacus transaction and his thoughts on client relationships in general, was even more counterproductive.

Even before the markets made earning outsize profits much

harder in the summer of 2010, Goldman Sachs was finding that it had to keep increasing the amount of risk it was taking in order to stay on top. Throughout 2009, the firm's average daily VaR level rose steadily, following a 20 percent jump in the fisrt quarter. Most of that came from its trading, particularly in the risky bond and currency markets. For most of 2009, the gap between bid and ask prices—known as the spread—remained extraordinarily wide, offering savvy traders the possibility of paying low prices to buy securities they could resell later at a higher price, either because the asset had risen in value or the spread had narrowed. Or, if the trader was executing a transaction for a client, wider spreads justified higher fees. In the second quarter of 2009, Goldman earned more than $100 million revenues on forty-six separate days of trading, according to an SEC filing—a record. Its value at risk shot up in the same period to an average of $245 million daily, from $184 million in the second quarter of the previous year. Goldman's profits drew irritable comments even from Wall Street insiders, concerned that the risks being taken to earn them would once again come back to haunt others who relied on the financial system. "They are making very luxurious returns," said Larry Fink, the founder and CEO of BlackRock and himself a former investment banker, of Goldman's profits. He went on to imply that this came close to profiteering at the expense of the money grid's users, including investment firms such as BlackRock.[3]

Every player cherishes his or her own dream of what the new Streetscape should look like. Some will find that vision harder to realize than others—Citigroup, for instance, will find it hard to reclaim all its past power and prestige. Regulators will have a tough battle trying to force legacy institutions like Goldman Sachs to change the way they think about their business. For others, the task will be simpler. All that is needed for some smaller firms to realize their vision is for Wall Street's giants to continue in disarray and confusion long enough for them to carve out a new and larger role for themselves during the morphing of the money grid. There is every incentive for the rest of Wall Street to continue chasing Goldman Sachs, in part because there is more opportunity than ever

before for some other institution to displace Goldman at the top of the Wall Street hierarchy by being just as smart and attracting less attention and controversy. Chasing Goldman Sachs could take on an entirely new meaning.

Wall Street's Barbell

As the panic that had gripped Wall Street at the height of the crisis in 2008 began to abate the following year, it was replaced with controversy. To avoid a repeat of the crash, what should the "new," postcrisis Wall Street look like? Should it be a completely fresh set of institutions, carved out of the strongest part of the legacy firms and supplemented by the array of midmarket firms and a host of boutique institutions and new players? Or should it be back to business as usual, only with a smaller number of ultralarge players dominating Wall Street?

As early as the autumn of 2008, it was clear that in the first stage of the evolution of a new Streetscape, at least, the financial system would look much like a barbell. At one end was a numerically small number of firms that, thanks to their gargantuan asset base, would likely continue to wield a disproportionate amount of power. These behemoths might be fewer in number than before—Lehman was gone; Bear Stearns, absorbed into JPMorgan Chase; and Merrill Lynch, now forming one division of the suddenly much larger Bank of America—but they would be powerful competitors. These "too big to fail" institutions also emerged as the focus of a controversy: should the government have shielded them from the full brunt of the financial crisis in the name of trying to protect the financial system itself from calamity? And would they continue to be handled with kid gloves because no one wanted to discover firsthand what might happen if they collapsed?

While the lion's share of the business—profits from underwriting stock and bond deals, advising companies on mergers, and providing trading services to clients—still rests in the hands of the giants, there is a lot of interest in what is happening at the other

end of the barbell, inhabited by a cluster of boutiques and specialized investment banks. Some are already established, like Sandler O'Neill or Jefferies; others have only recently been created by star bankers and traders who had decamped from the giant firms either before the crisis or in the wake of the chaos and upheaval. All of them are aware they have more chance than ever before of unseating some of the powerhouse firms and many are building their business plans on one incontestable fact: the distaste for and widespread distrust of "big Wall Street," exemplified by firms like Goldman and Citigroup.

Their potential clients may not subscribe to the kind of conspiracy theories put forth by Taibbi in Rolling Stone, but they do have lingering misgivings about the way those big players regard their clients in the wake of some of the disclosures in the FCIC and congressional hearings. Who wants to be the next IKB, the sucker who is fed a bunch of toxic securities by the next unscrupulous banker? The taint associated with old-model Wall Street is such that brokers and investment advisors who once loved to boast that they belonged to Merrill Lynch's "thundering herd" are now fudging their answers to the question "So, what do you do for a living?" Some are even deserting, setting up independent businesses.

"Some of the changes that we've seen happen in the wake of the crisis aren't likely to be unraveled any time soon, and they are changes that favor the creation of new business models on Wall Street," argues John Costas. He's putting his money where his mouth is. For more than a quarter of a century, Costas worked for some of Wall Street's biggest firms, rising to become head of investment banking at UBS. In the wake of the crisis, he launched the PrinceRidge Group with former colleague Michael Hutchins, a broker-dealer to trade a growing array of fixed-income products. But that's just the beginning of Costas's ambitions. He plans to turn to his advantage both the anger at Wall Street and the reality that the size of the "too big to fail" institutions can't serve all clients well; PrinceRidge, he calculates, is ideally positioned to fill what he believes is a void in the market left behind in the wake of the crisis.

"On a normal day in 2008 and into 2009, about half the market

share [was] up for grabs and the little firms were making ten times more money than they had ever made before," says Costas. He sees no reason that shouldn't continue and delights in the prospect of beating the big guys at their own game. Only weeks after opening its doors in 2009, PrinceRidge was off to a flying start; in 2010, it opened offices in Chicago and Los Angeles. "It's a very unique time, where you can open a business and right away have clients doing business with you." He sees no signs that the market opportunity is shrinking: while in 2006, about 85 percent of the trades that PrinceRidge is targeting were handled by the Wall Street giants, that ratio remains much lower. "Over the next three to five years, fifty percent or so will be up for grabs by firms like ours."

Hedge fund manager Nick Harris* is already seeing the impact of that trend. Harris relies on Wall Street traders to get him in and out of positions in stocks at a second's notice. Beginning in 2008, he realized that some trading desks at the giant Wall Street firms weren't as able or willing to help him put together trades as they once had been—even though Harris manages a few billion dollars in assets. JPMorgan Chase and Barclays (which acquired Lehman's investment banking operations) seemed to have little interest in changing that state of affairs. So when Harris set out to raise another round of capital, he embarked on a simultaneous quest to broaden his trading relationships.

"There's a great opportunity for anyone who is interested to come and grab market share in the trading universe—the Canadian banks, European institutions like BNP Paribas, or the midmarket firms like Jefferies," Harris says. "Anyone with any kind of appetite for risk and the ability to manage it could grab the business away." Previously, Harris had never dealt with trading desks at Jefferies or Key Bank. Now, he say, they "are starting to be more important to us because they are the guys providing the liquidity" in the place of giant institutions like JPMorgan Chase that reason tells him should be better able to do that. Harris now has a long list of those firms and individuals, including a relatively small Texas-based company that helped Harris execute some crucial trades in the stock of a tobacco company. That firm was added to speed dial on his traders'

phones; it took the spot once reserved for Citigroup, Harris says.

Forging a New Reality from Opportunity

Jeffrey McDermott has his own dreams of grabbing market share from the big institutions at the other end of the barbell. Unlike some other refugees from the Wall Street giants, McDermott initially thought he might launch a private equity firm when he left UBS in 2007. But raising capital as the credit bubble lurched toward its end proved difficult; McDermott switched his focus to a more distinct and more compelling business idea, and one he felt had a better chance of thriving: a boutique investment bank dedicated to advising and raising capital for clean technology and other green businesses.

"From the point of view of the economy and society as a whole, it was pretty clear to me that climate change and global sustainability were going to continue to be big areas of interest and investment for a while," McDermott explains. He calculated that, as had been the case in the dot-com revolution, smaller companies would likely lead the way. But with Wall Street's big firms caught up in the battle to return to their old business model and engaged in fighting off Washington's reform proposals, firms like Goldman Sachs weren't likely to be interested in any but the top 0.01 percent of those businesses, leaving, McDermott estimates, about three hundred companies in this arena "underbanked." Again, the upheaval had created a void—one that McDermott is filling with his new firm, Greentech Capital Advisors. He almost chuckles with glee discussing the magnitude of the opportunity, one that his years spent dealing with Fortune 500 clients at UBS prepared him to fill. "This whole industry has only grown up in the last (few) years, so there's no embedded firm with specialized knowledge and a competitive advantage. It's all new intellectual capital, and I'm in on the ground floor."

It remains to be seen whether players like Costas and McDermott can translate their early advantage into a lasting and sustainable

business edge. Dick Bove, an investment banking analyst who himself now works for a smaller firm, Rochdale Securities, argues that the big firms are likely to lose market share to the top new entrants. "The risk is on the side of JPMorgan Chase and the other big players," he says. "There's a space at the top of the investment banking world, where firms like Lehman, Bear, and Merrill Lynch once were—and yes, Goldman too, before it and Morgan Stanley became banks. That's the space that is up for grabs and it remains to be seen whether a new hybrid model—a firm more diversified than a traditional boutique, but that isn't driven by the need to post big returns on equity—will emerge and grab that, or whether it will be divided up between the big guys and the small, specialized boutiques."

Certainly, the boutiques showed no signs of standing still—on the contrary, they buzzed with excitement and a sense of opportunity. For years and sometimes decades, boutiques like Greenhill & Co. (founded by Robert Greenhill, former rainmaker at Morgan Stanley) had worked quietly but very profitably on the margins of Wall Street. With moderate fixed costs—they didn't run giant trading desks or have big underwriting or distribution businesses to fund—they had no giant debt load and while they hadn't been as locked into the pursuit of return on equity, they had done very well at the game nonetheless. (In 2006, when Goldman Sachs reported a 33 percent return on equity, becoming the envy of all the big Wall Street institutions, Greenhill generated an ROE of 56.3, rising to 82 percent in 2007.) It seemed to offer convincing evidence that trying to mimic Goldman Sachs was not the only way to become extremely wealthy on Wall Street. Greenhill never branched out beyond its core area of expertise and so, even at the height of the market meltdown in November of 2008, it managed to attract an extra $80 million in capital from investors eager to back one Wall Street business that seemed to know what it was doing. (It took only hours to raise the money; Bob Greenhill later bragged to Fred Joseph that he could have raised twice as much.)

The capital would come in handy, since Greenhill was taking advantage of the chaos to recruit discontented top bankers from

across Wall Street. From Merrill, Lehman, Citigroup, and Morgan Stanley, the bankers flocked to Greenhill and other boutiques, suddenly realizing that this was the kind of place he or she had always yearned to work. "It was obvious from the start that we didn't have to make the kind of tradeoffs—we weren't trading, we weren't lending, we were being hired for our expertise," says one banker who made the move in 2009. Greenhill acquired a Chicago office, and then opened one in Los Angeles as well, then expanded its roster of activities in London. The new bankers brought big deals with them: Greenhill advised Roche on its $46.8 billion battle for control of biotech giant Genentech. Not only were the boutiques avoiding the giant writedowns, but they were getting seats at some of the best deals in town: advising on InBev's $52 billion purchase of Anheuser-Bush; Pfizer's $68 billion bid for Wyeth; and the $58 billion merger of mining giants BHP Billiton and Rio Tinto. By mid-2009, their share of the merger advisory market had hit 15 percent—and that of the giants was down.

Some of the boutique bankers were focused not on chasing Goldman Sachs but rather on finding a way to reinvent the "old" Goldman Sachs for the twenty-first century. Ken Moelis, a veteran of such feisty second-tier institutions as Drexel Burnham Lambert and Donaldson, Lufkin & Jenrette, was one of these. Moelis became a power player at UBS, from which he walked away only weeks before the Swiss bank realized the full magnitude of its subprime lending problems. (Moelis wasn't involved in that CDO business.) Having turned UBS into a viable rival to Morgan Stanley and Goldman Sachs, Moelis figured he would repeat the feat—but this time for his own benefit. Now it would be Moelis & Co. that went head-to-head with Goldman Sachs.

At a Los Angeles dinner celebrating the new firm's launch, Moelis delivered a brief motivational speech to the small team of veteran bankers he had convinced to join him. It was clear that he saw the fledgling investment bank as something more than just another one of a cluster of boutiques. "I hope this is the beginning of something that, a hundred years from now, people will look back on and say, 'That's when it started.' " Moelis later recalled saying. In fact, he

thought it was the kind of moment that deserved to be preserved in the kind of old black-and-white photographs that had hung on the walls of the firms where Moelis had learned his trade and now set out to beat; the photograph featuring Messrs Goldman and Sachs, for example.[4]

Within twenty-four hours of opening his doors, Moelis had made the magnitude of his ambition clear, parlaying a long-standing professional relationship with Stephen Bollenbach, the CEO of Hilton Hotels, into a $13 million fee for Moelis & Co. in exchange for the new firm's assistance advising Hilton on the hotel chain's pending purchase by Blackstone. More deals followed and to be sure he was prepared for anything, he poached a forty-person team of restructuring bankers from Jefferies & Co. to handle what he expected would be a wave of bankruptcy-related workouts.

Even firms that had previously abandoned the investment banking and market-making parts of the financial services business seemed to take a new interest in their potential in the postcrisis environment. Sanford C. Bernstein & Co., noted for the caliber of its investment research, announced in December 2009 that it had recruited Thomas Morrison, a former Bank of America investment banker, to launch a new division that would focus on underwriting securities transactions for clients. This was a part of the business that Bernstein (now a division of asset management company, Alliance Bernstein Holding L.P.) had abandoned previously, amid controversy surrounding the potential for conflicts of interest between its research and the demands of serving corporate finance clients. Faced with the size of the opportunity that had arisen, those concerns now took a backseat.

The presence of these new rivals is an additional threat to the established banks, at a time when they already feel under siege by government policy changes. Some have let their frustration and vulnerability show, as when UBS filed a lawsuit against Jefferies & Company, claiming that the latter had been "surreptitiously planning" a raid on the former's banking talent before it poached a team of star health-care bankers. UBS had lost a lot: in the last four years, the team and its leader, Benjamin Lorello, had earned more

than $1 billion in fees for UBS. Given that the ties between a top banker and his clients tended to be stronger than those between the clients and whatever institution that banker happened to be working for (with the possible exception, of course, of Goldman Sachs), the suit showed just how concerned UBS was that its brand name not be further damaged by such defections.

The Future of the Behemoths

Wall Street's giant firms may feel threatened, but they aren't dinosaurs. Nor will they simply slink away into the night. For starters, many of them still have access to one of the scarcest resources on Wall Street postcrisis: capital. Underwriting deals is fine; advising on mergers is a great business. But to be a powerhouse player requires capital—and the talent to deploy it in such a way as to make money at every turn. "To stay in the game, you need capital," points out one Goldman Sachs banker. "Do you think that we just take an order to sell so many shares of General Electric [but] don't execute it until we find someone else who's willing to buy [the shares] at that price?" Nonsense, he says. Being an intermediary these days means knowing what price to pay for a big block of stock a client wants to sell, being willing to keep some, most, or all of those shares on the firm's own balance sheet ("warehousing" it, in Wall Street parlance) until a buyer can be found for it at a high enough price, and managing the risk associated with that position. That kind of market-making requires a big balance sheet as well as trading talent: two assets the typical boutique doesn't possess. "They're just too small," the banker says of the boutiques. "The phrase I hear is 'too small to thrive.' I don't know about that, but they'll be thriving in their own little corner of the world, not expanding into ours."

Whether that dismissive perspective is accurate or not isn't the point. Rather, the issue is that none of the rivals has a clear monopoly on the winning Wall Street model. Size has its advantages: being nimble and opportunistic will benefit other firms.

Even some of the firms that have struggled in the wake of the crisis have a chance at emerging in the winners' corner, once they are recapitalized and efficiently managed.

Still, by the time the dust settled it was clear that one of the large firms had a chance of beating Goldman Sachs at its own game. After years spent stuck beneath Goldman, Morgan Stanley and even Citigroup in the league tables and thus in Wall Street's pecking order, JPMorgan Chase was emerging as the dealmaker that its rivals were starting to envy by the summer of 2009. Of every $100 of fees companies paid to Wall Street banks for underwriting stock sales, JPMorgan Chase collected $15, while Goldman Sachs pocketed only $10. JPMorgan Chase vaulted from sixth to first place in the much-watched underwriting league tables since 2005, when it had earned only $5 of every $100 of fees. It was already a powerhouse player in the debt and loan markets, and its bankers were faring well in the battle to advise on mergers and acquisitions, helped by the bank's ability to make loans in support of these deals. (The battle between Goldman and JPMorgan for primacy continued into 2011.)

Moreover, the bank had relatively few legacy issues to deal with; whether by accident or design, its CEO, Jamie Dimon, had steered clear of the subprime mess; he had been tapped to acquire both Bear Stearns and Washington Mutual—deals which dramatically increased the bank's size and clout—because of its balance sheet strength. Almost overnight, Dimon became a kind of Wall Street superhero, one of the only Wall Street leaders to emerge untainted from the fiasco. At the firm's annual meeting in 2009, Dimon was thanked at least twice by shareholders for his leadership and was able to promise in return the prospect of a higher dividend.

The biggest banks face one giant obstacle, however: the raft of new regulations that I'll discuss in the next chapter, many of which will make it more difficult for them to take the kind of big risks that generate outsize profits. There is certainly a need for some kind of restraint: within a year of the crash, even the losers among the big banks were behaving as if they were winners and once again seeking ways to take risks that, if left unchecked as they had been

before, could create fresh havoc within the financial system. Citigroup, for instance, despite still having the government as its single largest shareholder after it had come closer than most other survivors to utter collapse, was mulling plans to revamp and relaunch its alternative-investments division before the first reform proposals announced by President Obama raised questions about its ability to do so. How risky might that have been? Well, one of the bank's former hedge funds had been liquidated in the wake of the crisis and had returned only 3 cents on every dollar investors had put into it—not a track record to inspire confidence in either the immediate managers or the bank officials overseeing the division. Happily, investors agreed that they weren't willing to climb back aboard this particular bandwagon: while Citi had hoped to raise $2.5 billion by 2010, at the end of 2009, it had received investor commitments for a mere $150 million. Perhaps investors will impose a kind of discipline on Citigroup's management that even near-bankruptcy failed to do? At least, that is possible for as long as those investors remain fearful. When memories of the crisis are less vivid, when greed returns and regulators become less vigilant, the system will once again be at risk.

For now, at least, everyone remains intent on ensuring there is no repetition of the events of 2008. "The regulators are hell-bent on not having this happen again," says Leon Cooperman, the former Goldman Sachs partner who currently heads a large hedge fund group. How can he be so certain? The very fact that they insisted that Goldman—along with Morgan Stanley—become a banking institution and subject itself to tighter levels of regulatory scrutiny. "When I was a partner at Goldman Sachs, we would sit around the partners' dining room and talk about how we never, ever wanted to become a bank; that the banks were too regulated, that the returns were much less in that business and what have you." And yet, that's precisely the path Goldman's leaders chose in September 2008. "You can rest assured that [they] became banks not because they wanted to, but because the government made it clear to them that was what was going to happen," Cooperman opines.

Even before the administration unveiled what would become the

Dodd-Frank Act in 2010, it was clear that regulators and policy makers wouldn't put up with Wall Street firms taking as much risk as they once had. Becoming bank holding companies meant that Goldman and Morgan Stanley came under the scrutiny of a new set of regulators and faced more restrictions on the amount of leverage they could deploy in the quest for profit. The Dodd-Frank Act, when it was passed in the summer of 2010, complicated matters further, putting another sizeable obstacle in the path of Wall Street institutions hoping to return to being profit-generating machines for the benefit of their shareholders and employees, as Citigroup's Parsons envisaged. If they can't pursue some of their most profitable business lines, and can't use leverage, then what?

"By and large, you can't make large sums of money without taking risks," comments Franklin Allen, finance professor at the Wharton School of Business. "The more money you make, the indication is that you probably took a lot of risk to do it.... And I think that's part of the problem."[5] Wall Street CEOs don't want to attract the suspicion of regulators by becoming extraordinarily profitable; at the same time, at some firms that have been slower to reembrace risk taking in the wake of the crisis, rumblings of discontent have been heard.

Morgan Stanley—the firm that forced out a former CEO, Phil Purcell, for being too reluctant to take risk—is now a much more conservative place to work, thanks to its new CEO, James Gorman. Before leaving that office, however, John Mack—who had insisted that Wall Street couldn't be trusted to govern itself—hired one hundred new risk managers. And yet bankers weren't happy that Morgan Stanley was taking longer to bounce back than archrival Goldman Sachs, meaning that bonuses would likely remain smaller. Some executives claimed that it wouldn't be long before the firm would be standing "shoulder to shoulder" with Goldman again, at least in terms of profitability and market share.[6]

But Wall Street is going to have to work harder and battle new kinds of rivals to earn the kinds of profits to which it had become accustomed in the first few years of the new century. The CDO machine is dead; the buyout funds are likely to be even more hard-

nosed when it comes to negotiating fees for advising them on acquisitions or underwriting IPOs of their portfolio companies. If the Dodd-Frank Act turns out to mean in practice what it appears to mean in principle, then Wall Street's institutions will be forced to rely on more plain-vanilla transactions to generate profits. That will be a good thing for the stability of the system—at least until Wall Street figures out a way to bypass the spirit of the rules while still adhering to them technically, and make money by marketing some new strategy or product or using some financial engineering technique that we can't even conceive of today.

The incentive exists to do just that, because those plain-vanilla transactions—the ones that are essential to the smooth functioning of the money grid—generate smaller fees, meaning profits will be thinner on the ground and shareholders increasingly dissatisfied. Goldman Sachs got a taste of that in the summer of 2010, when its return on equity dipped to a worryingly low 9.5 percent, a far cry from the 20 percent that Goldman leaders had always considered the base case and the 10 percent that is considered essential for a financial institution to prevent its existing shareholders from fleeing. If lower ROEs become the norm, Goldman and its rivals may yet—gasp—end up looking like a real utility.

Tug-of-War

The incentives for Wall Street to return to its past practices are all in place; the question that remains to be answered is what factors will rein in a repeat of that behavior. Regulators may place their faith in their ability to craft new rules but others, as I'll discuss in the next chapter, believe that a cultural transformation is required. But perhaps it will be the arrival of an entirely new kind of competitor that convinces Wall Street to keep its risk taking in check and focus on its core business. What if those firms that had been Wall Street's biggest clients over the last decade—hedge funds and buyout firms—now became its rivals? What if they began to try to serve as their own intermediaries and dispense with at least

some of the services of Wall Street's traditional money grid operators? Could a firm such as Blackstone replace Goldman Sachs and beat it at its own game?

It may sound outlandish, but buyout fund manager Jake Martin, who has been helping to structure financial transactions for a specialist buyout firm for nearly two decades, believes he and his peers have all the skills that are required. "I think it's quite possible that some of these large and very diversified buyout firms could bypass institutions like Citigroup altogether and sell bond deals for their portfolio companies directly to the buy side," Martin remarks. A firm such as KKR knows who the logical investors are for the debt it wants to issue to finance the purchase of, say, a medical devices company. "They have the same knowledge and skills as Citigroup—their ranks are full of bankers." Battered legacy institutions aren't attractive banks to work with, Martin adds. "At some point, it will be KKR and not Citigroup knocking on the door of other investors. They'll say, 'Hi, we're here to get you to buy a piece of this bond or loan deal, which we've taken a big piece of ourselves.' They'll be part investor and part banker, and the change will occur relatively seamlessly."

KKR is already taking baby steps in that direction. Back in 2007, it recruited Citigroup banker Craig Farr to build an in-house investment banking division, KKR Capital Markets, to serve the firm's own portfolio companies and give the buyout group more control over the whole investment banking process. In 2009, KKR Capital Markets signed an unusual pact with Fidelity, giving the investment giant exclusive access to KKR's share of any of its portfolio companies in the wake of an IPO or other public issue. This gives KKR an exit strategy for its holdings, and Fidelity the option to pick up some stock in any businesses that its money managers find intriguing without having to compete for them on the open market. Even more intriguing to many was the decision by Farr and KKR to provide the struggling Eastman Kodak with a cash infusion in 2009, a transaction that gives it the option to acquire a 17 percent stake in the firm down the road as well as two board seats—an unusual transaction for a buyout firm that prefers to own

a portfolio company outright. “Who knows where they could take this?” says one investment banker. “It’s not inconceivable that they could begin providing at least advisory services for a fee to Kodak now, and maybe develop more businesses for which they traditionally had to go to Wall Street. This is not a time to rule out anything.”

Martin’s own firm, which he didn’t want to name publicly, is already investigating ways to be its own banker. One option is to raise a new fund that would invest in bonds issued not only by its own portfolio companies (it already does that) but for other businesses as well. Instead of turning to Citigroup, the CEOs of those companies could cut out the middleman and come straight to Martin’s firm for capital. “Why do we need to have Citigroup as an intermediary?” Martin wonders, a small smile playing around his mouth. The smile broadens. “We can be our own intermediary; we have the know-how, the contacts. The technology exists to help us. And we have the kind of capital that we can put into these deals in a way that Citigroup obviously wasn’t able to manage to do sustainably.” In the postcrisis era, when Goldman Sachs’s brand name can be tarnished and an upstart bank like Jefferies can recruit a team of star bankers, why shouldn’t a KKR or a Blackstone transform itself into Wall Street power player? “If we do our own due diligence and say we’re putting our own money in alongside those of others, wouldn’t that be a selling point?” Martin demands. “I’ve got to believe it. After all, while Citi would only be interested in selling it on to the next guy, we’d be there for the long haul.”

Buyout funds may be pondering this kind of move, but at least one hedge fund began pursuing such a strategy in the immediate aftermath of the crisis. By late October of 2008, Ken Griffin, the founder of Citadel Investment Group, one of the world’s largest and most influential hedge fund empires, was preparing to take advantage of the carnage he was witnessing. True, Citadel’s own funds were being hit by losses, but Griffin saw these as being short-term hiccups. He was looking ahead to the day he believed Citadel would emerge as a new kind of player on Wall Street. The firm’s trading and market-making activities meant that it already

commanded as much as 4 percent of all trading volumes worldwide on any given day. Now Griffin figured he could put his firm on the same level as JPMorgan Chase or Goldman Sachs, and himself on the same level as Lloyd Blankfein or Jamie Dimon by leveraging that clout and market knowledge and becoming an investment bank in its own right.

Griffin confided his plans to Rohit D'Souza and Todd Kaplan, two Merrill Lynch alumni. Citadel's market-making division, a business that both offers to buy stocks, bonds, and other securities at a bid price and maintains an inventory of them to sell at the posted ask price, was the key. "It was clear to all of us early on in these discussions that the market-making business could serve as a hub for a new kind of investment bank," Kaplan recalls. "We started out by discussing what might be possible, and it quickly evolved into us working on a full-fledged business plan, on the way to add client-facing bankers to that existing model." Before the end of the year, Griffin, Kaplan, and D'Souza were all convinced: Citadel had a chance of becoming one of the great investment banks on Wall Street, they agreed. So what if it was technically still a hedge fund?

All three believed that the only way to try to launch a viable competitor to the existing investment banks, with their still-impressive (if battered) brand names, was to return to Wall Street's roots. Kaplan's vision was of an investment bank that would serve as an intermediary, not a principal; one that earned fees rather than using its own balance sheet to generating a return on equity. No more chasing Goldman Sachs, he decided. "I watched the big firms lose their way when it came to client service, and I don't want that to happen again." Whereas the classic investment banks had been sustained by the stream of revenues coming from high-margin trading operations up until Mayday in 1975, this twenty-first-century reincarnation of that model would be financed by the high-volume market-making business. (It didn't hurt that Citadel itself was making some $1 billion a year from the newfangled high-frequency trading platform it had built, a way to make even more money from rapid-fire computerized trading.) It was just a new twist on an old theme, some Wall Street veterans suggested as the

details began to leak out in the summer of 2009. But the one thing that stunned everyone was that the initiative was coming not from someone such as Costas or Moelis but from a hedge fund. From a hedge fund in Chicago to boot.

"I just don't see it," says Roy Smith, a finance professor at New York University and a former partner at Goldman Sachs. "How do they imagine they can achieve overnight what it took firms like Goldman more than a century to build?" Those who had studied Griffin as he built up a $15 billion hedge fund empire in less than two decades didn't want to underestimate him. "If he sees an opportunity, it's there," says one former senior colleague. Even though D'Souza and Kaplan had both bowed out by early 2010, the New York–based business was still growing and already working on trades for other hedge funds—something naysayers said could never happen—and had won mandates to advise corporate clients, including a bankrupt casino operator. Griffin sees himself not as chasing Goldman Sachs but rather as becoming Goldman Sachs. "I do believe in the next five years we will have created one of the great sales and trading operations" on Wall Street, he said in an interview.[7] And they will be able to do so, Kaplan argues, because returning to business as usual is neither possible nor wise for Wall Street as a whole. "This is a whole new ballgame."

Regardless of whether Citadel succeeds with its plan to graft an investment bank atop a hedge fund, Kaplan has come to believe that simply trying to emulate the Street's biggest and most successful firms was at the root of the crisis. Wall Street's institutions should have pondered whether or not they had a real competitive advantage in the businesses they were entering, he says, as well as a real understanding of the risks as well as the potential for those businesses to boost their ROE. "The need to make a return on the balance sheet was all-important, but then the balance sheet became the tail wagging the dog," Kaplan says. But while he believes a more classic model is the way of the future, he had trouble recruiting bankers who shared that vision, despite widespread layoffs across Wall Street. His in-box rapidly filled with résumés from displaced bankers with blue-chip pedigrees, few of

whom "get it," he explained. "When guys I talked to about a job asked me what our ROE target is, I had to explain we're not going to be managing the business that way."

Perhaps the biggest question about Wall Street today isn't the shape of the winning institutions of the future, but whether or not its denizens will ever manage to internalize that ethos. Certainly, government policies and new regulations won't succeed in swaying Wall Street's hearts and minds.

CHAPTER 9

Chasing Goldman Sachs?

A blizzard was blanketing the East Coast of the United States with snow on the day in late January 2011 that Phil Angelides and five of his nine fellow members of the Financial Crisis Inquiry Commission filed into a small conference room in Washington, D.C., to announce their findings. More than a year after beginning their inquiry—and months after the first package of financial reforms had become the law of the land in the shape of the Dodd-Frank Act—Angelides brandished the 545-page paperbound report in his left hand, pronouncing it to be the result of an exhaustive investigation into a financial system that had altered beyond recognition over the course of three decades until it was one that was no longer capable of discerning the course of action that was in the best interests of all the system's stakeholders. "The captains of finance and the public stewards of our financial system ignored warnings and failed to question, understand, and manage evolving risks," he said. "Theirs was a big miss, not a stumble. A crisis of this magnitude need not have occurred. To paraphrase Shakespeare, the fault lies not in the stars, but in us."[1]

The six members who had signed off on the report and now appeared before journalists to defend it argued that the crisis had been avoidable. Giant failures among regulators were accompanied by massive missteps and ethical shortcomings on the part of Wall Street itself, they declared. The financial system, they concluded, had become "a highway where there were neither speed limits nor neatly painted lines" and on which Wall Street firms had been conducting a giant game of chicken in the high-speed Porsches purchased with their lavish bonuses.[2] Group think dominated, a

majority of the FCIC members had recognized: instead of questioning what their rivals were doing, Wall Street firms blindly mimicked them in hopes of generating a few extra pennies a share in earnings each quarter. “A crisis of this magnitude cannot be the work of a few bad actors,” they proclaimed scornfully, dashing the hopes of those who had tried to pin the crisis on a handful of rogue mortgage lenders and their accomplices at now-defunct financial institutions rather than conclude that there was a systemic problem that needed to be addressed.[3]

But it wasn’t the blizzard that kept the other four members of the FCIC from attending the press conference. In fact, while Angelides and five other panelists (including former CFTC chair Brooksley Born) made their case for Wall Street’s culpability in the financial crisis, their report sparked not one but two separate formal dissents by the other members of their group—including disagreement over even including the phrase “Wall Street” in their conclusions.

Many critics of Wall Street had hoped that the FCIC would produce the contemporary equivalent of what became known as the Pecora Report, named for its primary author and chief counsel of the post-1929-crash investigation, Ferdinand Pecora. But while Pecora’s findings were so damning that he won the title of “the hellhound of Wall Street” for his relentless pursuit of the culprits who had undermined the integrity of the financial system, the FCIC was hampered from the start by the kind of sharp divisions of opinion of the kind discussed in chapter 7. Ultimately, these couldn’t be reconciled: some FCIC members could not or would not accept the idea that Wall Street was a prime mover in the near-cataclysm of 2008. Republican members fought, ultimately unsuccessfully, to have the words deregulation and shadow banking system removed from the report as catalysts for the crisis; in their eyes, the problem was tied to the role of Fannie Mae and Freddie Mac that encouraged reckless risk taking by mortgage lenders, as well as related government policies.

In order to reform the financial system—or any kind of system—you have to reach a broad agreement on what’s wrong with it and what needs fixing before you start tinkering in an attempt to fix the

problem. As the ferocious behind-the-scenes arguments between members of the FCIC showed, no such agreement seemed possible. While the Pecora hearings of 1933 and 1934 not only offered tremendous public drama but also generated widespread public support for sweeping new securities laws—including the Glass-Steagall Act that mandated the separation of commercial and investment banks—the FCIC hearings passed with relatively little commotion. As for the idea that the FCIC's conclusions might pave the way for thoughtful consideration of what kinds of reforms might be necessary for the financial system to continue functioning smoothly into the twenty-first century, well, the divisions among its members were enough to put that to rest.

Perhaps some of the skullduggery that was unveiled by the FCIC—Angelides told reporters that he has referred several names to law enforcement—will result in criminal charges. Perhaps, just perhaps, some of those charges will stick and someone will be found criminally liable for part of the crisis. But without any kind of consensus on what caused the financial crisis, the odds of reaching agreement on what to do to prevent a recurrence were sharply diminished. Now, with the crash in the earliest stages of becoming part of Wall Street's past history rather than its current reality, the odds that another crisis will rock the financial system to its core are creeping higher once again.

Back to the Brink?

The subtitle of this book, How the Masters of the Universe Melted Wall Street Down … and Why They'll Take Us to the Brink Again, warns of what happened when Wall Street couldn't govern itself and regulators weren't capable of reining in the Street's worst instincts … as well as what will happen if we don't find a way to do so in future. Optimists wondered why on earth that would happen again, given how close the whole system had come to complete collapse in 2008. "I think that some of the lessons will stick with us for quite a while, particularly as long as the leaders

who had to make the decisions about survival and who came within hours of filing for bankruptcy are at the helm and are in a position to see future problems in the early stages, before they become too big to control or contain," says one senior Wall Street veteran familiar with the thinking of leaders like Lloyd Blankfein and Jamie Dimon.

What optimists overlook is the fact that the conundrum at the heart of the way Wall Street works remains unchanged. As has been true for at least the last three decades, the pressure is on every bank and investment bank to identify and squeeze the last drop of profit out of each successive new product or strategy in order to maintain returns on equity at acceptable levels. Simply doing well isn't enough if one or more of your rivals is doing better. And there remain few incentives to ask the "risk question" along the way, to inquire, what happens if we all have it wrong?

Nor are there, as yet, any incentives for firms like Citigroup or Morgan Stanley to put the priority on running the money grid safely and efficiently in the interests of all stakeholders, not simply themselves and their shareholders, even though there is no evidence that the two objectives are completely incompatible. For now, CEOs at Wall Street firms may have been scared straight, but the system in which they operate and that doles out rewards to the overachievers among them and the punishments to those who lag behind is still the one that contributed to the crisis. So what is to stop a Wall Street firm from once again focusing almost monomaniacally on what is in its best interest, seeking out ways to earn even higher returns and recruit the top talent and offer the most enticing perks, paying little heed to the consequences?

Clayton Rose, a former investment banker who now guides students at the Harvard Business School through case studies of crisis and failure on Wall Street, is one of many veterans of the Street who worries that the reforms to date have been too cosmetic to effect real change. "There is a natural tendency to forget and to let self-interest rule the day," Rose says. When Long-Term Capital Management collapsed in 1998, requiring Wall Street firms to chip in $3 billion to "ring fence" that problem, "we thought it was the

end of the world," Rose recalls, "Now, that sum looks like tipping money, and the problem looks, in hindsight, completely containable."

Anyone looking for clues as to why Wall Street tends to self-destruct periodically, in large part due to its own foolishness, could do worse than pay attention to some of the details of the LTCM rescue package. Investment banks were asked to chip in $250 million each to save LTCM and thus the financial system; the fear was that a chaotic collapse of the hedge fund would pull its counterparties—the Wall Street firms that had done business with it—into the abyss one after another due to the magnitude and complexity of the counterparty relationships associated with its derivatives markets dealings. One after another, the big Wall Street firms agreed to participate in the bailout, with the sole exception of Jimmy Cayne of Bear Stearns, who flat-out refused. Merrill Lynch's then-CEO, David Komansky, demanded to know what Cayne thought he was doing. "When did we become partners?" a furious Cayne shot back.[4]

That attitude was still one of Wall Street's biggest problems a decade later, when then-Treasury Secretary Hank Paulson tried to drive home to Wall Street's leadership the message that they had a common interest that transcended their individual corporate self-interests during the fateful weekend in September 2008 that determined the fate of Lehman Brothers and Merrill Lynch. According to accounts of the meetings that took place at the Federal Reserve's headquarters in lower Manhattan, the assembled bankers pressed Paulson to structure a bailout for Lehman. For his part, Paulson tried to get them to shoulder some of the responsibility for what all were finally prepared to acknowledge was a systemic failure, and thus play a role in preventing a collapse that could have systemic ramifications. "You have a responsibility to the marketplace," Paulson told them.[5]

But once more, they declined to acknowledge that collective responsibility—whether they couldn't agree that they had a common responsibility in the first place (the concept that Cayne had so adamantly rejected in 1998) or whether they couldn't act on

it because of their own internal woes is unclear—and nothing happened. Lehman filed for bankruptcy protection, and the intermediary function at the heart of the money grid came within hours of not just freezing but collapsing altogether. "It's impossible to understate the sense of fear people in that room felt—they were going into the unknown," says one former top banker familiar with the weekend's events. He went on to compare it to the fear among scientists at Los Alamos just before the atomic bomb was tested for the first time in the early summer of 1945. "For all these guys knew, they were going to set fire to the earth's atmosphere when they set off the first nuke, and some of us wondered if we'd blast our financial system back to the days of the horse and buggy and the quill pen," the former banker says. "As it turns out, after Lehman, the government stepped in and did everything it could to make sure we never had to find out."

That attitude on the part of Wall Street—me first, me foremost, and only me—remains a problem today. They may have a common interest in fending off regulation or other outside interference, but Wall Street's firms have always seen a rival's woes as their opportunity—and vice versa. During the boom years, all of them had chased Goldman Sachs with zeal, thinking of little more than grabbing the biggest possible share of whatever fee-generating business was available, without considering the risk created to the system by the fact that they and their peers were all doing the same thing at the same time. Each firm on Wall Street put its own interests ahead of those of the system and paid attention to what its rivals were doing only insofar as those activities affected its own ability to grab market share and profits. (They certainly weren't thinking of the impact of so many firms following the same business strategy might do to the sustainability of that strategy, their business model, or the system itself.) The question continues to haunt some on Wall Street as well as many regulators who have used the events of 2008 to think more broadly about what went amiss—not just the proximate causes (why were so many subprime loans issued and repackaged into CDOs?) but more complex and far-reaching ones. Why was it that no one, even among those who

perceived the risks, thought to holler “danger”?

The Utility and Fiduciary Duties

To whom or what do the institutions at the heart of the money grid owe their primary loyalty? Should they have acted as partners to save the system, even at the last moment? Or, by 2008, was that kind of action so unimaginable that it had become impracticable? Without understanding how the denizens of Wall Street react to those questions, it’s impossible to address the logical corollary: Will anything stop Wall Street from returning to behaving recklessly once the crisis is past, even with more restrictive rules and regulations governing its behavior? What happens once the government is no longer peering over the shoulders of financial institutions that are now larger and more systemically important than ever—that have become, in popular parlance, “too big to fail”?

Unfortunately, in the absence of major changes to the DNA of these giant legacy institutions and their inhabitants, the question isn’t whether but when, as John Mack tacitly admitted in his cri de coeur. These firms have strong incentives to return to business as usual, and little motivates them to seek out a new business model, even if that new path might put less stress on the system as a whole. True, the advent of the Dodd-Frank Act means that regulators are now required to implement its provisions, a process that will mean finding ways to constrain some kinds of behavior on Wall Street. But regulation isn’t a panacea.

Even if Dodd-Frank did a perfect job of identifying the risks to the financial system—a claim that almost no one is trying to make—the legislation contains, as several members of Congress have pointed out, multiple unintended consequences for each one of its 2,500-plus pages. No one, for instance, wants Wall Street to curtail the “good” kind of risk taking that the money grid requires in order to fulfill its role in the economy—that would backfire, creating a system dysfunctional in a different way. Classic utilities such as gas

and electric companies may be economically and socially useful, but they aren't very profitable. One reason many on Wall Street recoil at their industry being characterized as fulfilling a utilitylike function is the fact that utilities' profits are typically overseen and its fees approved by regulators fearful that businesses running effective monopolies will take advantage of their customers.

Wall Street doesn't need to worry about being allowed to earn only a regulated rate of return, like their counterparts in other utilitylike businesses. To date, policy makers of all stripes acknowledge that Wall Street isn't a typical utility even if it exists to fulfill a social good of some kind, and that treating it as if it were a power or water utility might prove counterproductive. That is why they have so far tilted in the direction of letting the industry regulate itself, constrained only by the rules passed and overseen by organizations such as the Securities and Exchange Commission and the Office of Thrift Supervision. The problem is that as the financial system became more complex and more oligopolistic—by 2000, the ten largest banks held 40 percent of all commercial banks' insured deposits, double the level recorded in 1980—those organizations had become less rigorous in their enforcement of whatever rules existed. Meanwhile, the institutions themselves were paying attention to an altogether different set of incentives.

Unless you work for or invest in a power company, you can probably go through your entire life without becoming familiar with the phrase regulated rate of return. Similarly, unless you happen to be a corporate governance activist, a securities lawyer, or a corporate director, odds are that you've heard the phrase fiduciary duty only in passing and dismissed it as one of those bits of jargon that is just academic. That's only half true. While it is jargon, understanding the real meaning of the phrase is essential to grasping what happened on Wall Street and why it may happen again. The concept is straightforward enough: the idea that an individual or group has an overwhelming duty to another group that overrides every other possible interest, including self-interest. It's the same kind of relationship that a lawyer owes to his client, the kind that pops up during television crime shows when a lawyer

is put in an impossible bind when he can't publicly disclose information that would solve a murder because that information was entrusted to him in confidence by a client.

That is the level of duty that every director of every corporation owes to the company's shareholders. Every decision that a director makes must—legally—be in the best interests of those shareholders; that extends to the selection of the company's CEO. The CEO and the company's employees, in turn, are bound by the same obligation. The smaller the number of shareholders and the greater the extent to which those shareholders are the same individuals who serve as managers and employees—as is often the case in a startup company or in a private partnership—the more likely it is that everyone's interests will coincide. When a Wall Street firm is run by a CEO who is also a major shareholder—not just a shareholder but one who owns an outsize slice of the business—the odds are greater that that individual will be hyper-vigilant about the kind of risks and the nature of risks the company is taking. The greater the extent to which the people taking the risks identify emotionally with the company whose future they are putting at risk, the more they are likely to second-guess themselves. As investment banker John Costas has already noted, "The partners' capital was on the line; we thought about the long-term implications of all the business we pursued; we knew that our long-term profits depended on being responsible stewards of our capital in the short term." If a potential source of new profits seemed too risky over the long haul, Costas says, the partner had an incentive and even a duty to speak up and the ability to make his voice count, as one of those shareholders in whose interests the company was legally required to function. It was that kind of context that enabled Goldman Sachs to describe itself—with a straight face—as being "long-term greedy."

But what happened if the Wall Street firm's major investors weren't the firm's partners, those charged with its day-to-day operations? Even at those financial institutions where employees were, collectively at least, major owners—Lehman Brothers among them—the culture had changed over time. Few investors saw

themselves as long-term holders of any company, even the one they worked for at a given point in time. With the freedom to sell their stock in their publicly traded companies whenever they chose came an intensified focus on short-term profits. Even when restrictions were imposed on their ability to sell, many investment bankers found ways to hedge the risk that the value of their company's stock might decline; it was simple prudence. Accustomed to putting such strategies in place for their clients, doing so for themselves was a far simpler matter than trying to withstand the pressure to take on additional risk. Hedging gave them a way to have their cake and devour it at the same time: investment bankers could pursue the maximum profits possible (and thus the maximum possible bonus) and still limit their own losses to some extent. That helped them cope with the demands of their outside investors, all of whom seemed to have the clout to win an audience with an investment bank's CEO or chief financial officer—or even its directors—and influence decisions on how much risk to take in a way that a mere employee rarely could.

The very nature of Wall Street institutions as publicly traded companies has emerged as one of the chief problems, something that is perhaps a bigger issue in determining the health of the Street than the specific businesses targeted by the Dodd-Frank Act. If Wall Street firms came to rely heavily on proprietary trading, allocating big chunks of capital to create hedge funds and private equity funds, and seeking to develop increasingly complex and opaque derivatives, it is because these are the products and services that command the highest rates of return. Being accountable to a large number of outside shareholders came to be seen on Wall Street as a justification for pursuing the most profitable businesses, at all costs—and for chasing Goldman Sachs. In exchange for acquiring a larger and more stable capital base—the rationale for going public—investment banks found themselves with a new kind of burden. "The culture at Goldman Sachs began to change, almost to the day we finally completed the IPO," says one former Goldman partner. "More and more the discussion around new business opportunities wasn't about weighing the merits, risks, and profitability of the

business, but just about the profitability. There was still room to argue, but every day it seemed as if that was more futile."

Before Brad Hintz moved to Alliance Bernstein and began to track Wall Street's investment banks from the perspective of a research analyst, his job had been to communicate to investors that Morgan Stanley (in whose investor relations group he toiled) was doing everything it could to maximize profits and the all-important return on equity. As profits and outsize ROE levels became harder to earn, that message was simply that Morgan Stanley pledged to deliver "superior" returns. Increasingly, outside shareholders hearing this pledge defined the bank's fiduciary duty to them as earning and distributing the largest profits possible in the shortest possible time frame.

The pattern was the same across Wall Street. Each fiscal quarter, bankers at publicly traded investment banks scrambled to beat their own results of the previous three months to keep investors happy. And those big investors themselves—managers of pension funds, hedge funds, and mutual funds—weren't shy about making known their demands for ever-higher rates of growth in profits and ROE. One former Citigroup executive says, "That just didn't happen within a private firm. The pressures were there, sure, but there was more of a likelihood that someone worried about the long-term impact of a short-term move in market share could get a hearing and be heeded."

Other corporate scandals have rocked the United States in recent years, many of them involving managers who violated the trust of shareholders in the pursuit of personal profit. Some have revolved around the sale of faulty products; others, fraudulent accounting schemes. Ironically, no such betrayal can be cited as a cause of the financial crisis. Rather, as Leo Strine, vice chancellor of the Delaware Court of Chancery (a place where a great number of shareholder lawsuits are filed and adjudicated), points out in one of the most damning postmortems yet published on the Wall Street crisis, directors and managers were, if anything, too responsive to demands from their investors.

"The more pressure business leaders are under to deliver high

returns, the greater the danger that they will violate the law and shift costs to society," Strine concludes.[6] As of this writing, no one has been convicted of any criminal offense in connection with the crisis, a state of affairs that Oscar-winning documentary maker Charles Ferguson publicly deplored, to tremendous applause from the audience, when accepting his Academy Award for Inside Job, a film about the near-meltdown. It may be, as Strine cautions, that on today's Wall Street, firms "are free to engage in behavior that is socially costly without violating" the letter of the law.

To give the bankers at firms such as Merrill Lynch and Lehman Brothers their due, they don't seem to have set out with the explicit goal of destroying their firms. Rather, they lacked the imagination or intellect to realize what could happen down the road, or the skill to protect themselves and their firms from the fallout. But even if they had consciously behaved foolishly, a savvy lawyer could still argue—legitimately—that they were acting in the fiduciary interest of their investors. As long as those investors continue to believe that a firm's board and management are pursuing their best interests when they embark on strategies to maximize short-term profits—even at the expense of prudence—that is what those Wall Streeters will do. Missing from this equation is the kind of ethos that Dennis Weatherstone, former chairman and CEO of the firm then known as J.P. Morgan & Co., once tried to instill in the aggressive bankers under his dominion.

Weatherstone saw clearly the risk that one weak player within the system could destabilize Wall Street as a whole. Even if Morgan managed its own risk prudently, that couldn't insulate it from a firestorm, he realized. His realization was sparked by the rapid growth of the derivatives market, involving complex customized products; left to grow unchecked, Weatherstone feared what might follow since the system was only as strong as its weakest link. "If you are driving along the motorway in a smart Maserati and see an old car belching fumes, it's no good just driving on," Weatherstone told J.P. Morgan's young derivatives bankers in the early 1990s, according to Gillian Tett's chronicle of the bank's adventures in the derivatives world. Those fumes might signal a problem with the car

that could become a problem for everyone else on the highway. "If that old car crashes, it could wipe out the Maserati, too."[7]

But words of wisdom from such elder statesmen fell on ears that became increasingly deaf with the passage of years. As it became harder to make money by sticking to low-risk lines of business and plain-vanilla transactions on behalf of clients, the pressure to venture further into riskier trades involving the bank's own capital mounted. Often, that dovetailed with the clients' interests. For instance, proprietary trading was simply an outgrowth of market-making; the process of allocating the institution's capital to buying and selling big blocks of securities on behalf of clients. Those clients wanted the traders with whom they dealt to assume the business and financial risk of holding securities on the trading-desk balance sheet until needed by a client; they didn't want to be told they'd have to wait until the trading desk could line up a list of clients willing to take on the other side of the transaction. A bank that dithered about using its own balance sheet would lose business to rivals—the intolerable scenario. These days, no Wall Street firm can function only as a pure intermediary, veterans insist.

Some firms—notably Goldman Sachs—proved extremely adept at deploying their own balance sheets to maximum advantage. Others, faced with the harsh reality that raking in enough in profits to keep their shareholders happy via traditional intermediary businesses was no longer possible, concluded they would have to follow Goldman's lead. And they'd need to seek out other sources of large profits—even if those profits came accompanied by large risks—in order to stand a chance of offering their own investors a return on equity that came close to what Goldman Sachs could deliver. That's what Merrill Lynch and Citigroup were doing when they set up their CDO creation machines: taking risk to maximize shareholder value. The only consideration that would have weighed more heavily than that fiduciary duty would have been an outright and explicit ban on their involvement in the CDO business—a kind of blanket prohibition that remains unlikely today. Certainly, it was utopian to expect them to voluntarily refrain from taking on those risks, since that meant relinquishing the business—and the fees—to

their rivals. That would have been foolish on a personal level, especially once Phil Purcell's ouster from the helm of Morgan Stanley in a shareholder-led coup reminded every other Wall Street CEO of the career risk they were running by not pursuing the maximum possible profit.

What manager or board member, forced to choose between the possibility and even the probability of earning profits for investors in exchange for taking on some risk and the certainty of losing those profits to a rival by focusing too much on the possible risk would, in the absence of some flashing warning lights, decide to walk away from a deal? How could they feel they were on sound legal footing? "There was evidence that these businesses were profitable; there was no evidence that they were built on quicksand," argues one lawyer who represents one large legacy institution. "When there is no evidence of any E. coli or other tainted food, should a restaurant stop serving its customers steak or hamburgers" simply because history has shown that beef can be infected with the E. coli bacterium?

Certainly, John Mack didn't see the risks he was taking on so eagerly when he succeeded Purcell as CEO of Morgan Stanley. Some of Mack's earliest meetings were with the managers of hedge funds that were generating a growing proportion of Wall Street's revenues and profits. His mission was to reassure those managers that even though Purcell had favored sticking to the old vision of Wall Street as an intermediary, Mack had no problem with Morgan helping out its hedge fund clients by serving as a counterparty and taking balance sheet risk. As Charles Gasparino chronicled in The Sellout, his narrative of the meltdown, one of those with whom Mack met was Stanley Druckenmiller, manager of Duquesne Capital and a former colleague of the legendary George Soros. Morgan Stanley had what it took to replicate Goldman's trading prowess, Mack told Druckenmiller. "The old agency model is gone, and it's never coming back," Mack added. "The proprietary model is here to stay."[8]

As long as fiduciary duty remains a paramount consideration for Wall Street institutions, how possible is it to even think about

reforming the world in which these firms operate? The former Citigroup executive laughs at the paradox that creates. "Well, that's the 64-trillion-dollar-question. You'd like to think that the banks' directors and top managers would see that their fiduciary duty would stretch to include the well-being of the financial system as a whole, since without a Wall Street, who cares who's on top of the heap? But then, where is the evidence that that is happening?" Henry Kaufman, the onetime Salomon Brothers economist who won the nickname "Dr. Doom" for predicting the painful surge in interest rates in the 1970s and early 1980s, fears that there is only one logical outcome, even in the wake of the crisis. "Incentives to leverage [and risk taking] always will overshadow prudent judgments."[9]

The late Fred Joseph agreed with that assessment. "It's a bit inevitable, because that's human nature at work," he argued. "At least, it's the risk we all run, and hopefully we learn over time not to let our animal spirits run away with us. But it happens." Another Wall Street veteran, Peter Solomon, suggested to the FCIC that they at least revisit the merits of old-style Wall Street structures like the separation between risk-taking businesses and consumer-oriented ones (formerly mandated by the Glass-Steagall Act) or the private partnerships, as a way to limit the extent to which risk taking becomes destructive. "Our firm is a throwback to the era of the early 1960s when investment banks functioned as agents and fiduciaries advising their corporate clients," he said. (The italics are mine.) "We do not act as principals or take proprietary positions. We do not trade and we do not lend." That model, he suggested, has its advantages.

Perhaps the biggest problem of all is that by now, the current way of thinking about their business has been encoded in Wall Street's DNA. Once a Wall Street institution begins thinking of a 10 percent return on equity as unsustainably low and 20 percent as an acceptable number; once it accepts a certain set of growth and profitability targets as reasonable, it changes the definition of what is normal and what is excessively risky. Once it becomes accustomed to using a large balance sheet to help generate those

profits, once it relies on "financial ingenuity" to generate income, then it ceases to place as much value on the businesses that it once viewed as core to its raison d'être. And it becomes as hard for it to change its modus operandi as it is for a supertanker to change course on a dime.

Policing the System

Wall Street's instincts are pushing it in one direction, one that leads it back to the brink of the abyss as the need to earn profits pushes firms to take larger and larger risks. "Déjà vu is just around the corner," argues Leo Tilman, a risk management specialist. Back in September 2009, a year after the crisis peaked, Tilman reflected on what might lie ahead and predicted, accurately, that "calming markets and competitive pressures of fully commoditized financial businesses will compress margins and fees" once again.[10] (Within nine months, Wall Street's earnings would be visibly under pressure, albeit for slightly different reasons, such as client risk aversion.) Tilman predicts the vicious cycle will resume, with Wall Street's intermediaries taking risks they don't always understand and that they are rarely able to manage.

After decades working on Wall Street, Ralph Schlosstein, the CEO of boutique investment bank Evercore, has formulated a theory for what happens on Wall Street. In a normal year, the broad U.S. economy grows at a nominal pace—one that includes the rate of inflation—of about 5 to 6 percent. Yet somehow, as Schlosstein points out, investment banks consistently have managed to earn returns of between 17 percent and 20 percent on their shareholders' equity. In other words, their ROE has been anywhere from 11 to 15 percentage points higher than the rate of the growth of the economy. "If you're in a business generating that much more in returns than is being provided by the economy, you either have to find a way to give the excess capital you are making back to your shareholders [through dividends or stock buybacks] or you figure out some way to [use and ultimately] lose that extra capital by

involving yourself in some new business," Schlosstein says. Wall Street, he believes, has proven itself a master of the latter. "We lost money in the energy markets, in the emerging markets, in junk bonds, and now by securitizing subprime assets."

That this has been possible for so long is a result of two separate and converging trends on Wall Street. The first is the culture of Wall Street, described earlier in this chapter, and its increasing emphasis on generating the maximum rate of return for its shareholders on a short-term basis. The second is the kind of laissez-faire behavior on the part of those regulatory agencies whose mandate it was to rein in these institutions when they crossed the line and began to imperil the health of the system as a whole. Had it been possible for a Wall Street CEO to forgo a source of potential profits he believed to be too risky without jeopardizing his career; had Wall Street's culture been less of a "beat-thy-neighbor-at-his-own-game" affair and instead one where bankers worried that risk were taken seriously rather than escorted to the front doorstep of their companies, an investment bank might have been a less exciting but more stable place to work. But that isn't the case. So, in order to stop Wall Street from repeating its errors, we have two options, one of which seems impossibly complex; the other, deceptively straightforward.

The seemingly straightforward one is also the most appealing on a visceral level, especially to legislators who have to go back and face furious constituents at the polls: just slap more rules on the industry and throw the book at anyone who steps out of line. It's one that has attracted supporters from the White House (a furious President Obama made his first sweeping regulatory reform proposals in early 2010 in the immediate aftermath of the 2009 Wall Street bonus system) to, oddly enough, Wall Street itself. "Regulators have to be much more involved" in keeping an eye on what his firm and its rivals are getting up to, John Mack declared at the same time he made his astonishing plea for those same regulators to just jump in and stop him from behaving recklessly.

That was quite a statement, given that Mack, like his fellow Wall Street leaders, more traditionally has been an advocate of less

regulation, or, indeed, self-regulation. Nonetheless, it's a school of thought that, in one form or another had been gaining traction even before the president first introduced the proposals that would take formal shape as the Dodd-Frank Act, if only because it manages to shift the burden of responsibility from Wall Street altogether. "When you are sitting within one of these institutions, it's hard to even grapple with the concept of systemic risk," says Evercore's Schlosstein. "You are so focused on your own institution and how it is doing relative to its peers that it's hard to take enough of a step back to see the whole picture."

He grapples for the right analogy, one that will illustrate the kind of risk that is involved and the need for someone beyond Wall Street to shoulder the responsibility. "Imagine," he says, "that there's a wall, and on one side of it is someone with a giant canister of gasoline. On the other side of it is a guy with a giant match. Neither of them can see the other or know that the other is doing something that places them both at risk." A regulator, Schlosstein explains, is the only person in a position to not only see what both of these individuals are doing but also understand whether the gasoline is being stored safely so that no lit matches will cause it to explode, or whether the person on the other side of the wall is playing with his matches in a way likely to cause a conflagration.

"In banking, we train people to react to a problem by finding a way to make money out of it," Schlosstein points out. That's what hedge fund manager John Paulson did when he became a billionaire after identifying the weaknesses in the mortgage and CDO markets and finding ways to exploit them in the financial markets. He believed that subprime lending, poor structuring of CDOs, excessive leverage, and inadequate capital were about to wreak havoc on Wall Street, but his instinct wasn't to warn Lehman or Bear Stearns or to shout his findings from the rooftops. Rather, Paulson set out to sell short the securities he believed would suffer most in the crisis, just as, in the depths of the crisis, he became an active buyer of stock in big "legacy" financial institutions, betting that the survivors would rebound. That bet has paid off, too. Paulson, like any other short-term investor, is risk-agnostic—as long

as the risks he take pay off, he's happy to be at the party in any capacity.

Mack and Schlosstein are right when they argue that more active and more thoughtful regulation of the money grid is needed to stop a repeat of the events of 2007 and 2008. But for all the lavish praise President Obama and others heaped on the Dodd-Frank Act when it was passed in the summer of 2010, that package of proposed reforms—all 2,500 pages of it—is no panacea. Harvey Pitt, former head of the Securities and Exchange Commission and now the CEO of a Washington-based consulting company, Kalorama Partners LLC, argues that there are three fundamental flaws with the legislation, aside from all the unintended consequences that we can't yet quantify or even identify.

Firstly, the new law doesn't require any entity whose dealings could have a big impact on the financial markets to provide an ongoing stream of data on their operations to regulators, so that the latter can monitor risk. (A new body of federal regulators can monitor or unwind any systematically important financial firm, but that's not the same thing, Pitt points out.) "We've got a problem today in that we regulate people by looking at what they were born as, rather than what they have become over time, and that leaves a lot of regulators without enough knowledge of how the firms they monitor actually can impact the financial markets," Pitt says.

Not to mention the fact that—at least hypothetically—should Goldman Sachs one day decide that it's fed up with having federal banking regulators peering over its shoulders and second-guessing all its decisions when it isn't even a "real" deposit-taking bank, the firm could opt to bid farewell to its banking license and reinvent itself as something else, thus escaping from some of the regulatory scrutiny now following it. That may not be likely or even probable in the current climate, but it's not impossible, particularly a few years down the road.

Then, as regulators are already aware, there is the fact that new kinds of entities, such as hedge funds, can have a disproportionate impact on the health of financial markets and yet go largely unregulated. Several years elapsed between the LTCM implosion in

1998 and the first successful effort to get the biggest hedge funds to begin disclosing even rudimentary details of their operations to regulators.

That's not all, Pitt says. Once regulators have that information or the raw data, it needs to be properly analyzed and shared efficiently with other agencies, "so that regulators and those in the markets themselves can factor it into their decision making." Finally, he says that some kind of circuit breaker mechanism needs to be put into place that will get government regulators "to stop, look, and listen to what is going on and prevent the trend from continuing and magnifying until we can understand what it is that is really taking place and identify any systemic threats." These three ingredients, if combined, would have contributed to regulatory reform creating a nimble system able to respond to financial market crises as they are building, rather than after they have begun to claim casualties, he believes. "Together, these would give us some level of comfort that the next crisis will be manageable."

Rather than being nimble and flexible—the ideal, in the eyes of Harvey Pitt and many of his former regulators—the reforms enshrined in the Dodd-Frank Act tend to be more static rules. The bill as a whole, argues Allan Meltzer, professor of political economy at Carnegie Mellon University "is a terrible bill. Yes, it corrects a lot of problems that are of some importance to someone, but it doesn't correct real causes of the crises" such as the "too big to fail" issue and the moral hazard that accompanies it, he says. Static rules tend to be those created solely in response to the last crisis, such as Glass-Steagall in 1933, which responded to the problems of risk-taking by deposit-taking financial institutions by requiring the rigid separation of the two kinds of institutions into investment and commercial banks. That did help to stabilize the financial system—until it didn't anymore. Under siege for the last half of its sixty-six-year existence, Glass-Steagall ultimately wasn't flexible enough to respond to the changing realities of the banking system—specifically, the need of financial institutions to consolidate in order to become more efficient in a globalized, fast-moving, and capital intensive business.

The Dodd-Frank Act does address some important issues. It provides for the creation of a systemic regulator and creates a Financial Stability Oversight Council that will possess sweeping powers to investigate any potential risk to the health and well-being of the financial system. It intensifies the oversight of hedge funds and introduces the "Volcker Rule," which imposes limits on the degree to which a financial institution can use its own balance sheet to take bets in the hopes of boosting its own earnings. In other words, the Act aims to limit the extent to which a bank can treat itself as its own best customer, by refusing to allow it to allocate more than a sliver of its assets to hedge funds or private equity funds, or indulge in proprietary trading to any significant extent. The Act tries to ramp up oversight of the over-the-counter derivatives business and also provides for the creation of a consumer protection agency charged specifically with ensuring that ordinary individuals aren't abused by the financial institutions in the fine print of credit card deals, mortgage loans, or other financial products.

The ideas behind these and the other detailed reforms spelled out in the fine print of the legislation officially known as the Dodd-Frank Wall Street Reform and Consumer Protection Act are often laudable. But there are countless obstacles that litter their future path. Firstly, they must be implemented; specific policies need to be designed by the agencies charged with carrying out the reforms. We have already seen in the fierceness with which parts of the market battled specific provisions that were later dropped or watered down in the Act, that Wall Street won't sit by waiting to abide humbly by whatever new rules Congress and regulators choose to devise. As always, they intend to have a voice in shaping those rules, and they had some early successes—removing car loans from the oversight of the new Consumer Financial Protection Agency, for instance. While banks will only be allowed to dabble in derivatives for the benefit of their own bottom line if they are hedging positions already on their books (such as Treasury bonds), there are loopholes which could permit them to set up separate divisions that would still be able to undertake those trades. There's

no mention of Fannie Mae and Freddie Mac, the two government-sponsored entities that have been on life support since the crisis and which fueled the mortgage bubble by allowing and encouraging their balance sheets to swell with new home loans.

"For every provision of the bill that tries to stop Wall Street from doing something it has been doing, there are several loopholes and even more ways for me to challenge the law," says one financial services lawyer who brags about having become wealthy by challenging the provisions of Glass-Steagall and who anticipates a similarly lucrative future chipping away at elements of Dodd-Frank that his clients find restrictive. One area that will certainly be the focus of a lot of scrutiny is the debate over what actually constitutes "proprietary" trading. There is likely to be a sharp difference of opinion among some regulators, who view the extensive market-making operations of Goldman Sachs, for instance (which can involve holding large positions of all kinds of securities on the firm's trading books for significant periods of time) as proprietary trading, even as Goldman's executives insist it's all about catering to their clients. No wonder the Dodd-Frank Act "lends itself to being called the lawyers' full employment act of 2010," as Harvey Pitt gloomily dubbed it.

An effective regulatory system is one that is dynamic. As well as having rules that restrict the worst kinds of risk taking as well as illegal or abusive behavior by the industry being regulated, the regulatory system must be able to spot trends as they take shape and determine whether they might pose a real danger to the health of the financial system or even just to the well-being of a single systemically important player; it must be able to react in an appropriate fashion, rapidly enough to make a difference. An effective regulatory system is one that functions as a counterweight of sorts to Wall Street's "animal spirits." When a bubble of any kind arises, particularly when a new kind of business starts generating a disproportionate amount of profits for Wall Street, regulators must be able to understand what is going on and to react appropriately.

Consider for a moment two entirely different kinds of regulatory failure by Alan Greenspan, the once-revered Fed chairman who was

idolized so much by financiers that a rumor he was ill or dead was able to rock financial markets during his reign in the 1990s. In late 1996, Greenspan correctly identified that a bubble was taking shape in speculative dot-com stocks and warned of it publicly, referring to "irrational exuberance" on the part of market participants. But it took more than three years for that bubble to burst, during which time it grew to extreme levels and claimed many more victims. What might have happened had Greenspan gone beyond "jawboning" and instead had summoned the CEOs of the major financial institutions involved in the emerging bubble to a meeting and told them he didn't want them to underwrite excessively speculative companies and that if they persisted, they should be prepared to contribute a share of the fees they were earning to an investor protection fund? Flash forward to 2006, a period in which the credit bubble was already well in place—a bubble that this time Greenspan didn't appear even to notice. What would have happened had such a revered figure even decided to speak out and voice concerns about mortgage fraud and excessive leverage on Wall Street?

In both cases, all that would have been required to make Wall Street CEOs sit up and take notice would have been a gentle hint that someone like Alan Greenspan—a figure with unparalleled power and the gravitas of a Warren Buffett—was worried about what was happening. That kind of finger, applied in the right place at the right time, may have steered the financial system out of harm's way whether by causing Wall Street's leaders to act themselves or prodding them to pay some heed to the concerns of in-house naysayers like Lou Gelman at Morgan Stanley during the dot-com era (who had watched his role morph from that of gatekeeper to the capital markets to one he compared to being a croupier at a Vegas casino) or Mike Gelband at Lehman Brothers, who tried repeatedly to win a hearing from his bosses on his concerns regarding the firm's exposure to real estate.

Good regulators think countercyclically. When they see the boom taking shape, they worry about the bust that could follow. Just as a good utility regulator makes sure that a Consolidated Edison power

plant has enough generating capacity to serve the citizens of Manhattan on the hottest summer days—that it can cope with a week or two of every citizen running his air conditioner at maximum power twenty-four hours a day without a blackout—so a good financial regulator will make sure that the institutions it oversees have their own version of excess capacity in the form of large capital reserves. Those can't be fixed, simply defined as a function of the type of bank it is or even by how much risk now-discredited models tell us the institution is running with its capital. Rather, capital adequacy standards need to adjust with the institution, so that a bank that suddenly starts paying outsize bonuses to employees in a new business segment that could potentially put at risk a lot of the institution's capital is required to set aside more of that capital to guard against such potential losses, even if nothing else has changed. If that new business line suddenly begins to generate a third of the company's revenues or profits, that might trigger additional regulatory scrutiny and possibly additional capital requirements.

The idea, says Sheila Bair, the head of the FDIC, is to make the kinds of business strategies that proved so destructive in the first decade of the new millennium so unappealing and costly that Wall Street firms will shun them on their own, without being required to do so, or at least manage them more carefully in the future. "One way to address large interconnected institutions [those deemed too big to fail] is to make it expensive to be one," Bair suggested to the FCIC. She proposed that giant banks should be required to contribute to a fund that could be drawn on to finance the breakup of a systemically important firm that starts to fail, arguing that such a proactive approach would be better for taxpayers than an after-the-fact emergency capital infusion or bailout. It also gives a firm a financial incentive to avoid failure in the first place.

The more risky a bank's business model—the more it relies on proprietary trading or structured finance, like CDOs or derivatives—the higher its "insurance" payment would be, Bair proposed. She went further still, suggesting that the "too big to fail" institutions should be required to draw up a kind of corporate living will that

would include a plan for their own liquidation in the event of insolvency. Again, the intent of proposals like these is to require those on Wall Street to ask the "what if" questions that too often get shoved to the bottom of their agendas.

A lot of attention has been devoted globally to the issue of capital standards. This is crucial: had financial institutions not eroded (sometimes deliberately, in order to magnify rates of return on equity) their capital bases in the years running up to the crisis, far fewer banks would have failed, required bailouts, or even wobbled, experts agree. Prior to the crisis, the average large global financial institution had set aside about 2 percent to 3 percent of their capital in the form of common stock as assets that could not be used or invested, that had to sit on the bank's books ready to plug a balance sheet hole. Under proposal G-20, which policy makers put forward last autumn, that level will rise to 7 percent or so and regulators will have the flexibility to tell the institutions they oversee to boost that by another few percentage points should they detect another credit bubble in the making. The fact that regulators of the nations in which the major financial centers of today are located are all collaborating to devise an appropriate capital standard means that it will be harder in the future—at least as far as can be determined today—for banks wishing to cut their capital reserves to the bone to simply shift their businesses to another regulatory jurisdiction, or to argue that they need permission to set aside less capital in order to compete with rivals in other jurisdictions.

Good regulations are those that will cause an institution being regulated to stop and ponder the nature of the business that it is pursuing; to second-guess itself; to ask itself tough questions, such as, "If I am wrong about this, what is the worst that can happen and am I prepared as I can be for that and for whatever consequences follow?" The hallmark of a poorly conceived regulation is one that has all and sundry devising ways to outwit it before it has even been passed into law, such as the elements of the Dodd-Frank Act that try to regulate the derivatives business. The goal was to get many of these instruments traded on an exchange or at least cleared

through some kind of intermediary organization, a step that would make it simpler for market participants and regulators to identify potential risk. That's a laudable objective. But lawmakers wanted to exempt some players from this oversight. Farmers, mining companies, and others use relatively straightforward kinds of commodity-based derivatives to hedge their day-to-day business risks rather than to speculate. A farmer, for instance, may lock in a price for his soybean crop long before he harvests it by selling soybean futures; that eliminates the risk he will see his income plunge before he can harvest as the market reacts to the prospect of a bumper crop.

As long as those who are exempt from that law really aren't speculating and they have an economic purpose for their actions, that's fine. But quite apart from the possibility that exempt players would suddenly be given carte blanche to do whatever they want, without the kind of supervision other market participants face (and ignoring the fact that some of them, like the world's giant energy or mining companies, are big enough players to merit monitoring), there is a big additional risk. What is to stop Steve Cohen at SAC Capital, for instance, from opening a division of his hedge fund empire devoted to oil and glass exploration and production? Once established, with the exemption given, would the rules prevent the hedge fund from routing all kinds of derivatives transactions through this new division?

It's hard to see how the trade-offs and compromises necessary to pass regulatory reforms like the Dodd-Frank Act will result in a series of new regulations and regulatory bodies that are capable of meeting the extraordinary demands that will be placed on them in the years ahead. It isn't a matter of the perfect being the enemy of the good; rather, the question is whether the good can ever be good enough. Even in the best possible situation—one where the new rules themselves are good—the success of regulators will hinge on their ability to attract and retain the best talent and thus be able to enforce those rules. In other words, agencies like the SEC—in an era of government-budget cutbacks and renewed partisan hostility to regulation—needs to begin chasing Goldman Sachs on its own turf.

To be effective, regulators need to be as aggressive and as knowledgeable as the best Wall Street bankers. Too often, the savviest regulators are lured away from the SEC and other agencies to work at the financial institutions they once regulated—the fox that once guarded the henhouse has been recruited to devise strategies for future raiding parties. What regulator will be willing to take a hard-line stance against the big financial institutions, while being aware that down the road, in order to repay her student loans and put her children through private school and college, she may be approaching those same organizations in hopes of landing a much more lucrative job? For the money grid to function in the interests of all its stakeholders, regulators who ensure the rules are being applied in the best interests of the system deserve to be rewarded lavishly for containing risk, just as bankers and traders are for running those risks or helping their clients manage them.

Chasing Goldman Sachs?

At the end of the day, the question boils down to whether Wall Street's reckless risk taking can be constrained by force alone, in the same way that criminal psychologists believe a serial killer is doomed to repeat his behavior unless confined to a maximum-security prison for life or sentenced to death. That seems to be what John Mack was suggesting when he declared "we can't control ourselves," and what the rhetoric that accompanied the financial reform proposals has implied. When Charles Prince put forth the same case, he did so somewhat more poetically, arguing that as long as the music kept playing, he had to keep dancing and keep pace with everyone else.

But isn't it ever possible for someone on Wall Street to break step and decide to sit out the dance? And if not, why not? And if not, what can we, collectively, do to make that possible? While we can use the regulatory system to shield us and Wall Street from the latter's worst instincts and protect the money grid, surely we are all better off in the long run if Wall Street can develop its own modus

operandi for managing risk and corraling "animal spirits."

It's impossible—and undesirable—to remove greed as a factor in the way that Wall Street thinks and operates. Even John Mack, for all his newfound zeal for reform, believes that isn't a good idea. "We cannot and should not take risk out of the system—that's what drives the engine of our capitalist economy," Mack told the FCIC commissioners during their inquiry. But perhaps it is possible to devise ways in which greed can be displaced as the sole deciding factor. Instead of playing yesterday's game, chasing Goldman Sachs in the hope of earning the highest possible profits, could financial institutions shift their focus to emulating the best characteristics of Goldman Sachs?

Doing so would require Wall Street leaders to ponder the reasons that Goldman Sachs became the firm that everyone else on Wall Street envied—why it always seemed able to be ahead of the curve whether it was a matter of identifying promising new businesses or avoiding new sources of risk. The mystique predates the tenure of ex-Goldmanites Robert Rubin and Hank Paulson at the helm of the Treasury Department, giving the firm perceived "insider" status in Washington. Long before it had the easy access to cheap government capital that turbo-charged its earnings power and attracted controversy in the aftermath of the crisis, it was earning a higher rate of return and paying out heftier bonuses than its rivals, year after year, with fewer missteps.

In the late 1990s, when other firms decided that catering to the man in the street or the retail investor was the wave of the future and set out to either build or acquire retail brokerage networks, Goldman Sachs dismissed the idea. Goldman wasn't Merrill Lynch; that wasn't its core business. It was a firm that worked with institutional clients—big pension funds, mutual funds, or companies in search of capital—and a handful of ultrawealthy individuals and families, but not Joe Sixpack. That wasn't a business it knew, and it came with a set of risks the Goldmanites didn't feel sure that they could manage. Sure enough, within a few years, the Internet craze was over and several of the firms that had made massive investments in developing a broad retail presence were forced to

retrench or refocus. Goldman had never jumped on that bandwagon, and it let the next one pass it by as well. When firms such as Merrill Lynch were snapping up mortgage-origination companies in order to secure as much proprietary deal flow as possible for their CDO-creation machines, Goldman Sachs once again decided to stick to its knitting—even when it was criticized by shareholders for not chasing this possible source of profits.

But Goldman didn't stop at not jumping into the CDO business with both feet; it spotted the risks far earlier than most of its peers, and devised ways to limit its losses and to even profit from what it expected would be a downturn, even though those strategies landed it in hot water later on. Over the course of a two-and-a-half-hour meeting on December 14, 2006, that has now become part of Wall Street's folklore, chief financial officer David Viniar met with key members of Goldman's mortgage underwriting team, its risk managers and its traders, and emerged with the conviction that this was indeed a bubble, and one that needed to be shorted. Goldman reduced or removed the amount of credit it was willing to extend to mortgage originators. It established short positions in the credit and derivatives markets that would boost its profits if the real estate market began to crumble, and it began to sell off its own holdings of mortgage-backed securities, both subprime and investment-grade, in transactions like the Abacus deal.[11]

Goldman Sachs and its employees are no saints, as the Financial Times noted when it named Lloyd Blankfein its Man of the Year in 2009. The firms that bought the CDOs they had structured and sold were clients—Goldman was their counterparty and didn't owe them any fiduciary duty. As Blankfein told his interrogators within Congress, these were mainly professional investors who could look out for themselves. That's not an argument that will boost the public's perception of Goldman Sachs, but while the investment bank may have been in morally muddy territory, it was doing just what its obligations to its shareholders required it to do, not bending over backward to disclose more to clients about these transactions than it believed was absolutely required by law. Did anyone really expect a Wall Street firm to suffer from a sudden

attack of altruism? Or expect Goldman Sachs to warn the world about Viniar's conclusions? After all, John Paulson didn't issue a press release when he established his own positions. It was up to Goldman's clients to look at the same set of facts—they were there for anyone alert and astute enough to spot them—draw the same conclusions, and take the same measures. Most didn't, as history would quickly demonstrate.

What is worth chasing about Goldman Sachs isn't its rate of return; what is worth replicating isn't its outsized bonus pool. Rather, what the rest of Wall Street can learn from Goldman Sachs is that strategic thinking and planning of the kind that Viniar and his team displayed in the runup to the crisis pays off—and can pay off disproportionately well when done by some of the smartest people on Wall Street. "Trying to simply mimic Goldman Sachs is likely to lead to disaster," says Evercore's Schlosstein. Rather, he and others suggest mimicking elements of their strategy.

That, says another former senior Wall Street figure, is harder than it sounds. "When I talked to people who worked for me, I would ask them to come and tell me what their strategy was going to be for next year; how they were going to change the business and adapt to the changes that they found," he recalls of his first years overseeing a business division. "Don't tell me you're going to run faster than everyone else, shoot straighter, and win. Because that is not ever what works on Wall Street, not ever." The harsh reality of life on the Street, he adds, is that few people look ahead very far and think strategically; even fewer try to combine that analysis with a hardheaded evaluation of their own competitive strengths and weaknesses. "There may be a lot of very smart people on the Street, but they are always playing yesterday's game or today's game, not thinking about tomorrow," he says. "They are not thinking about how the markets are changing, how they might change in the future, how they can organize today to prepare for that."

The result is that when change happens, Wall Street scrambles to cope, just as it did when new technology wreaked havoc on its business model and just as it did when Mayday removed—overnight—the stable source of trading fees that made that business model

sustainable. “Because they are clever and smart, these Wall Street guys from the better firms, they develop a solution and survive,” the banker-turned-consultant says. “But it’s not done in such a way that they plan ahead and try to control the outcome and position themselves to win. It’s not that Wall Street discourages strategic planning; it just doesn’t reward it. It’s all about what is this year’s performance, or how did your group do last quarter? It’s about maximizing this year’s bonus, and worrying about next year when it happens.” To the banker, a chess player, it’s like the difference between a game of poker and a game of chess. At poker, he says, what happens in one hand doesn’t affect the outcome of future hands—that’s a function of the cards he is dealt. Chess, in contrast, is a game of strategy, where each move limits future options or creates fresh opportunities. “It doesn’t surprise me that the guys on the Street tend to play poker more often than chess,” he comments drily.

A handful of Wall Street players do appear to be pursuing business in the Goldman Sachs style. In the autumn of 2009, in a move that received almost no attention from the financial press, the firm founded by star banker Robert Greenhill, Greenhill & Co., calmly announced that it would spin off its proprietary private equity investment division, Greenhill Capital Partners. At least one firm, it seemed, had decided that trying to emulate Goldman Sachs by becoming bigger and more diversified and doing more proprietary deals wasn’t the only path to success on Wall Street. Greenhill was thinking strategically, and had decided to play to his own firm’s strengths: advising clients on mergers and other strategic moves. “The scale of the opportunity,” Greenhill declared, “merits our undivided attention.” This, Greenhill had decided, was where his firm could capture higher profits, where the skill of his bankers could make a difference.

As every innovative new product that Wall Street devises becomes commoditized and while access to capital is, in normal market environments, already a commodity, skill is the one thing offered on Wall Street that is likely to continue commanding a premium fee. It is skill that helps Goldman Sachs earn a substantial

return on its shareholders' equity, and that will help it navigate financial markets that have been more tricky since the summer of 2010. Skill, like strategic thinking, can be acquired and honed, but not imitated or chased. Nor can strategic planning. Clayton Rose says that Greenhill's move was not only a reflection of the boutique institution's clear understanding of its skills but also a recognition of its weaknesses. These insights can only come from strategic thought. "Smaller players [like Greenhill], in this environment, don't enjoy a competitive advantage in terms of access to credit or deal flow for their private equity or merchant banking businesses," says Rose. "So they don't have the ability to outperform their larger investment banking peers in this area" on an ongoing basis.

If you can't beat them, why chase them at all? That's a question that we have too rarely asked Wall Street firms or, it seems, that they have too rarely tried to ask themselves. The firms that now dominate the money grid—JPMorgan Chase and Goldman Sachs—do so because they have a culture that puts a priority on risk management, and part of that risk management process involves asking tough questions of oneself. Some of the firms that chased Goldman Sachs without a real understanding of what made its model work—as opposed to what kinds of businesses helped it generate big profits—are now gone, or absorbed into other institutions.

So far, too few Wall Street firms have tried to answer the question of why they're chasing Goldman Sachs, much less the broader question of what Goldman Sachs represents. Some of those who have done so have come up with the wrong answer, judging by Dick Parsons's throwaway comment about Citigroup's priorities; others don't see any reason to undertake that exercise at all. When these firms are once again on stable footing, will they resume chasing Goldman Sachs—or JPMorgan Chase, if that firm succeeds in unseating Goldman and emerges as the model to emulate on Wall Street? Will smaller rivals try to replicate what Goldman Sachs has done, rather than carve out their own path to success based on their own strategic analysis of the opportunities and challenges and their own strengths and weaknesses?

"There is significantly more capital on the books of Wall Street's banks than is needed for them to fulfill their core role of providing liquidity to investors," says Evercore's Schlosstein, alluding to one of the basic utility functions at the heart of the money grid. As long as that is the case, he adds, there will remain an incentive for parts of those firms to take outsized risks and to behave as if they are running a casino rather than a utility. "Something needs to provide Wall Street with a wake-up call and remind it that shocks like those of 1998 and 2008 will not be aberrant events as long as the risk-taking culture remains so central," Schlosstein argues. "Memories fade faster on Wall Street than on Main Street."

But Main Street's need for Wall Street is the reason that Wall Street still exists. The one certainty is that, regardless of which particular institutions or investment banking models endure and triumph over the next decade, its functions must remain intact. Unless we want to return to the days when we had to save for decades to buy a house, couldn't buy furniture for that new home until we had saved the cash, and had to keep our savings in a bank account paying us less in interest than the rate of inflation (or, worse still, buried in the backyard or in our mattresses), we all have a healthy interest in ensuring that Wall Street functions smoothly, just as we have an interest in being sure that when we flick a switch, the light comes on, or that clean water flows through our taps.

That means we have a vested interest in ensuring that Wall Street begins to adopt some kind of long-term strategic planning, that it collectively stops trying to chase Goldman Sachs and instead starts trying to emulate the best features of the Goldman Sachs model. At the same time, all the financial institutions that collectively make up the money grid—including Goldman Sachs itself—must accept that as long as they collect the profits from running the grid, they must be prepared to pay the price when things go awry. A system in which the intermediaries profit or are cushioned from the full impact of any disasters while those at either end suffer outsize losses is not one that is sustainable.

Going forward, all of those who have an interest in the survival of

the money grid that is Wall Street must decide collectively what kinds of actions and compromises are necessary to ensure that the grid and its functions remain healthy and vibrant over the long haul. Otherwise, we risk a systemic meltdown that could make us look back on the events of 2008 almost wistfully. Ultimately, we will get the Wall Street that we deserve.

GLOSSARY

Active/Passive investing: An investor may actively choose what stocks or bonds to add to a portfolio, or can opt to put money into an index fund or exchange-traded fund that simply tries to replicate the composition and performance of an index. The latter is referred to as passive investing, and die-hard advocates believe that since few managers can reliably outperform an index (after fees) over the long term, it's always the better option for investors.

Alpha: The ultimate big-game hunt on Wall Street is the quest for "alpha." Technically, it's a return that can't be explained by what's going on in the market. So if the S&P 500 is up 10 percent and a manager posts a 15 percent return, that extra 5 percent is, theoretically at least, pure alpha. The problem is that the more you look for alpha, the harder it is to find, just like your missing car keys. Some folks argue that it's less like big game and more like looking for the dodo bird—in other words, it has been hunted into extinction by all the hedge funds.

Arbitrage: The process of taking advantage of small price differences between the same kind of investment in different markets.

Asset allocation: The process of dividing a portfolio among all the possible asset classes or types of investments, with return objectives and risk and volatility concerns in mind. A basic asset allocation involves stocks, bonds, and cash; it can also include other asset classes, such as real estate and commodities, and subdivide an asset class into subcategories with different characteristics—for instance, emerging market stocks, growth stocks, value stocks, small cap stocks.

Asset-backed securities: Bonds that are based on some kind of

income-generating asset—a mortgage, credit card receivables, or even a rock star's royalties. The income a bond investor receives is the cash flow from that asset, translated into an annual interest rate.

Back office: The behind-the-scenes operations necessary to the smooth functioning of any business, financial institutions included. Typical backoffice operations include clearing, information technology, human resources, and risk management.

Beta: The return that is offered by a market index, such as the Standard & Poor's 500 Index. (See alpha.)

Black Swan: An event that most market participants dismiss as so unlikely to occur as to be almost improbable. The events of 2008 reminded everyone that just because such events may not be visible most of the time doesn't mean they can be safely ignored. (See tail.)

Bonds: A bond investor is lending money to a company (or a government) for a fixed period of time and usually at a fixed rate of interest, which is why these are also referred to as fixed-income securities. A bond is a liability—investors are creditors, who are entitled to a stream of income but don't have any ownership interest in the entity issuing the bonds unless that issuer defaults, or stops paying the interest. In that case, bondholders may force the issuer into bankruptcy and seize the assets posted as collateral for the bonds. Bonds tend to earn lower rates of return for investors than stocks, but to offer less risk.

Capital: The lifeblood of any business, capital is the amount of cash, investments, and other assets on its books. To be well capitalized, a business's assets and liabilities (its debt, amounts owing to others) need to be in balance. But banks detest holding large capital reserves on their books; even though it's important to protect their balance sheets from losses on loans (see default).

every dollar set aside is a dollar that isn't working to boost revenues and profits. Part of Wall Street's problem in 2008 was lack of access to long-term capital at a time when the value of other assets on its balance sheet was eroding, after Wall Street firms themselves had pared their capital levels to the bone.

Capital markets: Those financial markets that are used to help raise capital for corporations or other entities (including the U.S. Treasury), or in which the securities created to finance the companies' need for capital change hands on stock markets or via over-the-counter networks, are collectively referred to as the "capital markets."

Career risk: A wry term coined by those on Wall Street to express the kind of non-financial risk they run by making a decision that others see as risky. For instance, someone running a mutual fund was far more likely to run "career risk" by putting money into an unproven dot-com stock than by investing in a blue-chip company—even if the outcome proved identical. One catchphrase embodying this idea was "No one ever got fired for buying [shares in] IBM."

CDO/CLO: A security that is made up of a pool of other securities, and that is then divided into tranches or slices that have different risk and return characteristics. A CDO, or collateralized debt obligation, is made up of debt securities, such as mortgages or car loans, while a CLO, or collateralized loan obligation, is a pool of loans.

Clearing: When a buyer and a seller of stocks, bonds, or other securities come to terms, there's a back-office process that follows, in which the owner of the securities transfers them to the purchaser in exchange for the money agreed on. The process results in what's known as the "settlement" of the trade.

Collateral: The security posted by a borrower that can be seized by

a creditor if the borrower defaults on a loan. In a mortgage, the collateral is the house that is being mortgaged, for instance.

Convertible: Not all securities sold on Wall Street are straightforward debt (in which the investor gets the right only to agreed-on interest payments over the life of the security and repayment of the principal. Some are hybrid securities, known as convertible bonds or convertible preferred stocks. These start their life looking like fixed-income securities, offering the investor a steady stream of income, but can be converted later on into stock.

Correlation: A way of describing the likelihood of event A being followed by event B, expressed in numerical terms. A perfect correlation means that if one thing happens, another is almost certain to happen as well, either at the same time or in short order. Investors use correlation to understand what the risk is that a hike in interest rates will cause not only a selloff in the bond market but also in the stock market—and which parts of the stock market might be less correlated to interest-rate jumps and thus a safer place to seek shelter. In the midst of the financial crisis in 2008, nearly all assets were tightly correlated, falling in tandem, even many of those that had historically displayed much lower levels of correlation. (See diversification.)

Counterparty: Literally, the individual or entity taking the opposite side of a trade or transaction. When you buy a house, your counterparty is the seller. It's an arm's-length kind of relationship, in contrast to the word client, which implies an ongoing relationship that includes an element of trust.

Covenant: The terms and conditions under which a loan is granted or that are specified in a debt security. A borrower may be legally obligated to keep a certain level of assets or cash flow relative to the value of the loan, for instance. Violating a covenant—even if the borrower has kept up with payments—can put that borrower

into default.

Credit: The origin is credere, Latin for “to believe”; and credit signifies the belief that a borrower will be able and willing to repay what has been loaned. To extend credit is not only to make capital available (at a certain rate of return) but to signify confidence in the borrower.

Credit default swap: Developed in the 1990s as a way for banks and other financial institutions to reduce their exposure to credit risk (the risk that a borrower can’t repay his loan, see default). The pressure was on banks to keep less and less capital in reserve to guard against defaults. Like any swap, the CDS seeks to move a set of risks from someone who doesn’t want them to someone who sees a profit in them. A bank might buy credit default swaps to protect against loan losses—with the counterparty paying up in the event of a loss, but collecting a fee immediately in exchange for that longer-term insurance. For banks, it was a great way to reduce exposure to some kinds of commercial loans without damaging client relationships—they could extend a moderately risky loan, keep the customer happy—and then use a credit default swap to reduce the risk of that loan. The original credit derivatives involved single-company credit risk; credit default swaps packaged together multiple corporate credits.

Default: When a debtor—a company that has issued debt securities or taken out a loan—ceases to make regular interest payments to the lender as provided for in the loan agreement or under the terms of the debt security, that entity is deemed to be in default. As a company’s cash reserves decline and its finances come under pressure, the risk of default rises, usually triggering a slump in the price of both its shares (which could be worthless if default presages a bankruptcy filing) and any debt securities. Cash flow is the major warning sign of a looming default.

Derivative: A security whose value is linked to, or derived from,

that of an underlying asset. For instance, gold futures contracts are tied to the value of gold bullion; stock options are linked to the value of a stock, and move in response to any stock price change. They are contracts on myriad financial products, which can be as straightforward as gold and crude oil futures, or as complicated as customized swaps involving obscure currencies. Farmers and mining companies can use derivatives to hedge their risk, selling forward their future production and locking in a guaranteed price. But speculators can also use derivatives—both exchange traded and customized—to bet on what they think the financial markets will do.

Diversification: The process of spreading assets around many different kinds of investments; much research has shown that diversification can lead to higher investment returns and limit risk.

Due diligence: Don't trust; verify—that's the mantra of the financial markets. And due diligence is the process of checking a company's books for hints as to how strong its business really is, looking for any unexpected hiccups or errors in judgment. It's the process usually undertaken by an acquirer before purchasing a business, in the same way that a homebuyer will ask a structural engineer or other expert to check that a house they want to buy doesn't have termite damage or other flaws before they complete the transaction. In the stock market, due diligence by investors can mean checking regulatory filings and other financial disclosures, talking to people in the same line of business as the target company, interviewing executives, etc.

Futures: Contracts between a buyer and a seller (purchased/sold on an exchange) in which a buyer promises to pay a fixed sum for a fixed quantity of a certain asset at a date in the future. (Hence the moniker.) These began as a way for farmers to hedge the uncertainty of crop prices—they could sell wheat that was still growing months before it would be harvested, locking in a price.

Futures started as a way to trade commodities, but today include contracts on interest rates movements, currencies, and many other kinds of assets and are now used by investors with no interest in taking delivery of a bushel of soybeans or barrel of oil to speculate on the future movements of those commodities.

Glass-Steagall: The 1933 law that mandated the separation of commercial banking (banks that take deposits and make loans to "ordinary" individuals) and investment banking (a riskier and more volatile business involving trading and underwriting). Passed in the wake of the 1929 Crash and the banking crisis that followed, the idea was to create an environment where the backbone of the financial world would be sheltered from similar storms in the future. But long before it was eventually overturned, Glass-Steagall was eroded by decisions such as that by the Federal Reserve in 1990 that enabled banks to resume trading securities.

Hedge fund: Go anywhere, invest in anything, but bring back an eye-popping performance. That's the theory that underpins the existence of the hedge funds. Very few of these funds were structured as "hedges"—to minimize risk. The moniker seems to have more to do with the use of short-selling, one hedging technique that can also be used to generate profits. Over the years —multi-strategy. And as the landscape became more crowded, there were fewer unexploited opportunities. These are private partnerships, lightly regulated, that typically offer their managers the opportunity to profit from their investment skill by rewarding them with not only a management fee but a percentage of the profits.

Hedging: An investment strategy used to manage an existing risk. If someone works for Microsoft and owns a lot of Microsoft stock, he or she might use options to hedge against a decline in Microsoft's stock price, for instance.

Illiquidity: An environment in which it's nearly impossible to get

market prices on the securities in a portfolio because there is little or no trading in those securities, and so it becomes extraordinarily difficult to determine the value of a portfolio. (See liquidity.)

Incentive fees: The fee that a manager of a hedge fund or buyout fund collects if they hit a certain rate of return. In a typical structure, the manager might get 2 percent to manage the assets, but pocket 20 percent of any profits as an incentive to do well.

Index: A collection of securities brought together because they reflect a certain kind of asset class or category and can be used as a shorthand way of describing the performance of that group of securities. For instance, the Standard & Poor's 500-Index is a proxy or reflection of the performance of the largest U.S. publicly traded corporations of all kinds. Various products can be structured to allow investors to profit from moves in an index, from index funds and ETFs to swaps.

Institutional investor: The opposite of a retail investor (see below), an institutional investor is an entity or an individual responsible for managing large pools of capital that don't belong to him or her personally. An institutional investor can be a mutual fund manager, or in charge of running a college endowment or pension fund's assets. They are the investors who, due to the billions of dollars they control, dictate the direction and velocity of the financial markets.

IPO: This stands for initial public offering—i.e., the first time that stock in a particular company has been sold to general investors via a large-scale transaction. Up until this point, financing is deemed to be "private"—a handful of institutions or individuals known to the company have been approached to provide funding. An IPO is an opportunity for those early investors to reduce their holdings by selling them at a profit. An IPO typically means that the new stock will now be traded on a stock

exchange, and its shares, available for purchase by anyone at all with the money and the interest in acquiring them.

Junk/high-yield bond: When a company's credit rating is low, it has to pay higher rates of interest in order to issue debt because the risk of default is seen to be higher. Hence, these companies issue what investors might describe as "high yield" bonds, a polite description that refers to the level of interest payments, or "junk" bonds, referring to the credit quality.

League table: The lists published periodically—every quarter, every year—showing the market share of banks and investment banks in key areas such as stock and bond underwriting and merger advisory mandates. Financial institutions measure their market share and relative performance using these rankings.

Leverage: Basically, this means borrowed money. When you buy a house and take on a mortgage to finance it, you're using leverage. On Wall Street, leverage is most frequently used to turn a trade that on its own is only slightly profitable into one that becomes much more lucrative. If you have $10 but can borrow $90, you now have $100 to invest. If you make $1,000 with that $100, you have a much larger profit—you only have to return that $90 (plus whatever interest rate you paid). You really used only $10 to generate $1,000, so your actual rate of return is far higher.

Leverage ratio: Ratio of how much a financial institution (or other entity) has borrowed for every dollar of equity on its balance sheet.

Limited partner: An investor in a private equity, venture, or hedge fund (in Wall Street terminology, at least).

Liquidity: The lifeblood of any business or individual. You may feel rich if you own a Picasso painting, but if that's all you own, you don't have the "liquidity" required to pay your mortgage or buy

groceries. Liquidity measures how much cash you have on hand or readily accessible, in an emergency. Even solid businesses can succumb to a liquidity crunch if panic makes it impossible for them to access capital or sell assets to finance operations—transactions that could readily have been accomplished in a normal environment.

Loan losses: The amount of capital set to one side to protect a financial institution against losses on the loans it has made to its clients.

"Long": Stock market jargon for owning a security outright and betting that its price will climb. If you buy 100 shares of Microsoft, you are "long" the stock and hoping that its value will rise.

Margin: The process of borrowing money to buy securities and using those securities as collateral for the loan. Margin is often offered by brokers to creditworthy clients. But borrowers can face margin calls if the securities they have bought on margin fall in value, pushing down the value of the loan's collateral.

Mark-to-market accounting: The process of adjusting the value at which securities are held on the balance sheet of a bank or an investment bank based on the price others are willing to pay for them. That's a straightforward task when it involves stocks, since the price is openly revealed by the stock exchange on which a stock trades. It's trickier when it involves private companies or "over the counter" securities for which no public market exists. (See over the counter.) "Marks" can fluctuate dramatically, depending on the willingness of buyers to invest; sometimes the market that owners think is there doesn't exist at that price at all. Marking to market is an important discipline because it identifies any gaps between the value someone applies to an asset and its real market value, but only when those doing it find ways to value those hard-to-value assets (like subprime CDOs in the midst

of a market selloff).

Market-making: At its purest, market-making involves a financial institution bringing together two investors that separately want to take the opposite view with respect to a particular security or investment idea; the institution serves as matchmaker and facilitator, collecting a fee for being the intermediary that helps to price and execute the transaction. In practice, market-making can be murkier; a bank can buy assets from a client and keep them on its own books for some time. Is that proprietary trading (see proprietary trading) or market-making? It all depends on who is making that assessment. Certainly the bank can claim it is simply facilitating a client's desire to execute a transaction and taking the other side of that trade until a counterparty can be found. But that's not always the full picture.

Maturity: In financial markets, this term is used to indicate the life span of a security such as a bond, futures or options contract, or other structured product. A bond that matures within twenty years has a long maturity; one coming due within the next year has a short maturity.

Models: Designed by highly skilled computer geeks, these were used as the basis for managing risk and predicting reward. Quantitative investors, for instance, used models to screen for stocks they believed had characteristics to outperform; risk managers used models to try to predict future losses in the event of such events as sudden interest rate increases, a boost in the price of oil, or other factors that might affect the value of a portfolio or trading book. The problem is that many models rely on assumptions gleaned from data; they can thus be tweaked to produce a desired result or have flaws that only show up in times of crisis.

Moral hazard: When someone perceives that there may be no negative consequences for taking risks, they are likely to take

more or greater risks. That implicit "get out of jail free" card is dubbed moral hazard; critics charged that government bailouts create a moral hazard for the rest of the financial system by altering behavior and attitudes to risk.

Mutual fund: A pool of capital offered by a management company (such as Fidelity or T. Rowe Price) available to any investor. An investor can buy or sell at any time over the course of a day, making mutual funds liquid. They can be broad (for example, investing in U.S. stocks) or narrow (investing only in European technology companies).

Off-balance sheet: The process of shifting assets and liabilities off a company's own balance sheet and onto that of another entity, sometimes a subsidiary of the company. Doing this can free up capital and make a company's own balance sheet—and debt and leverage levels—look more healthy.

Options: The right, but not the obligation, to purchase a security at a specified price and a specified date in the future.

Over the counter: While most stocks are traded on an exchange, many other securities change hands only via a network of traders or dealers, what is referred to as "over the counter." Some of these OTC markets are very liquid, such as government bond markets, as the trading is heavy and frequent, with many participants. Other securities, however, are much more exotic or customized, have only a few natural buyers or sellers, and therefore can't be readily bought or sold. (See liquidity.) Some never trade at all. An illiquid OTC security can be very difficult to price. Even if a liquid market was present a month ago, events can cause that liquidity to dry up rapidly and, in contrast to the stock market, there are no players required to continually "make" a market in a given security.

Par: A term used in the pricing of bonds and other fixed income-

style securities, this refers to the value of the assets being sold at the time of their sale. For instance, a $100 bond that is sold for its full face value, $100, is said to be sold or priced "at par." In some cases, bonds are sold above or below par at the time of issuance, but more often the move away from par value comes in the secondary market and is a reaction to the move in interest rates (a rise in interest rates often pushes the value of already-issued bonds offering interest payments below the new, higher level lower in price) as well as the credit quality of the issuer. A bond trading at 75 cents on the dollar, for instance, is trading "below par."

PIK, or payment in kind: A twist on interest payments offered by cash-strapped businesses. Instead of making interest payments in cash, they might offer them in more debt or stock. It's a riskier investment as instead of pocketing cash, the investor is agreeing to accept a security whose future value may be uncertain.

Plain vanilla: Jargon; a slang phrase used to describe a very straightforward security or transaction. The original swaps contracts were "plain vanilla"; many credit default products of the 2005–2008 period were anything but.

Price: As in every other market, it's something that buyers and sellers haggle over daily and varies depending on the appetite of the buyers for whatever kind of security or asset is being put up for sale, as well as the amount available.

Private equity fund: Based on the theory that public financial markets don't always fairly reflect the full value of a business, private equity funds use borrowed funds to buy businesses and overhaul them. The goal is to find ways to enhance or make more apparent the real value and then sell them to the public via an IPO, or to another corporation in a "strategic" merger.

Proprietary trading: This is the phrase used to describe the growing

trend of banks and investment banks to set aside a portion of their own capital for their own traders to deploy as they see fit in pursuit of profits. Most of their other businesses involve the financial institution serving as an intermediary, helping buyers meet sellers. In proprietary trading, the bank itself becomes one of the parties to the transaction, rather than just facilitating it. During the 1990s and into the first decade of the twenty-first century, this became an important source of both profits and market intelligence for many institutions.

Quants: Quantitative investors rely on data and models to tell them what investments are most likely to outperform in any given market situation. Quants are usually very skilled in building computer-generated models and related fields; often referred to as "rocket scientists," some have, indeed, used their mathematics and physics skills working for NASA and other organizations.

Rating agency: When investors don't have the resources to do their own due diligence or don't want to invest the time and energy required to understand the risks of a security, a rating agency is a fallback. In the runup to the crisis of 2008, however, too many investors had placed too much reliance on those ratings—and the rating agencies had compromised their standards in order to pull in fees and enrich themselves. Rating agencies have had a privileged role on Wall Street, thanks to regulations requiring institutional investors to buy "rated" bonds.

Repo market: By 2007, investment banks used the repo market to fund half of their assets, obtaining short-term capital from big institutional investors who are willing to entrust them with that capital because the investment banks put up collateral in exchange. The problem was that the risk associated with those assets began to climb in the months leading up to the crisis; eventually, repo lenders insisted on bigger discounts and ultimately dug in their heels and refused to lend, even overnight, against assets that couldn't be valued and that were highly

volatile. A crisis of confidence produced a liquidity crunch. This was the late-twentieth-century version of a run on the (investment) bank.

Retail investor: An ordinary individual saving for his or her own retirement or other goals; not someone who is managing money on behalf of others as a professional.

Returns: The size of the profit an investor makes on their investment, usually expressed in percentage terms. For instance, buying a stock at $10 that then climbs to $12 within six months would mean a six-month return of 20 percent.

Return on equity: This figure, known as an ROE, tells investors how skillfully and effectively a company's management team is employing the capital they have invested to generate profits. It is a particularly significant metric for anyone trying to understand how well a financial services company is doing in absolute and relative terms.

Risk: When we cross a road, we run the risk that we'll be hit by a car, trip over a curb, bang into another pedestrian, or have the bottom fall out of a bag of groceries. The risks confronting financial-market participants are equally varied, and far harder to track. They are also linked. (See correlation.) Some risks that financial-market participants must bear in mind are price risk, volatility risk, economic risk, operational risk, credit risk, and counterparty risk.

Risk-adjusted return: If two investors each earn 15 percent on their portfolios over the course of the year, who is doing a better job? One way to answer that question is to figure out how much risk they are taking to earn that 15 percent; the investor taking less risk is earning a higher risk-adjusted rate of return. There are many different ways of calculating this kind of figure and some element of risk-adjusted returns has crept into the evaluation of

most kinds of investment funds.

Risk management: The process of understanding and seeking to limit or reduce the magnitude and nature of risks being run by any entity. Increasingly, on Wall Street, this involved using derivatives to break up risk and package it out among more different institutions—the theory was that such a spreading out of risk would minimize any shock to a particular institution.

SEC: The Securities and Exchange Commission, established in the 1930s to ensure that public securities markets function efficiently. Companies are required to disclose earnings and other material facts; the SEC is charged with guarding against insider trading and other wrongdoing.

Securities: A way of referring to the whole panoply of financial assets—stocks, bonds, loans, et cetera.

Securitization: The process of taking a loan and turning it into a security that can be traded by packaging it together with many other loans of a similar kind, then selling ownership stakes in the entire loan pool. Securitization started with mortgages, then moved on to car loans, credit card receivables, even rock star royalties.

Shadow banking system: Entities that make up the shadow banking system don't take deposits, like a traditional bank (e.g., Citigroup or JPMorgan Chase), and include investment banks, hedge funds, and mortgage lenders, as well as money market funds and other nonbank financial players. They serve the same intermediary role but are more lightly regulated.

Short-selling: To bet against a company's stock or other security is said to be selling it short. Instead of buying a stock and holding it outright, a skeptical investor borrows the stock from an institution that owns it. then sells those securities. She is now on

the hook: at some point, she will have to repurchase the stock and return it to the institution that lent it to her and meanwhile she is paying a fee for borrowing it. For the transaction to be profitable, the stock must fall. The lower it tumbles, the cheaper it will be for her to buy back and replace—the difference between the price she sold it at and the price she buys it back at is her profit. If she gets it wrong, the loss is potentially unlimited, one reason why many brokerages limit the amount of short-selling a client can do and require short-sellers to demonstrate a degree of market knowledge.

Spread: The difference between the yield on one asset—say, a Treasury bond—and another, such as a junk bond. The wider the spread, the riskier the higher-yielding asset is said to be.

Stocks: Purchasing stock in a company gives an investor an ownership interest in the business, in contrast to a bond. While companies can pay dividends on their stocks, investors typically make most of their return in stocks from capital appreciation: the growth in the value of the stock.

Stress test: A process in which the managers of a financial institution run "what if?" scenarios and gauge their organization's ability to respond and even survive anything from a computer-systems crash to a massive and unexpected change in interest rates, market valuations, or other factors. Playing around with scenarios can highlight previously unknown or underrated sources of risk.

Structured finance: The process of and the players involved in developing often complex, new kinds of securities to transfer risk from one player to another.

Structured Investment Vehicles (SIVs): Off-balance sheet entities in which financial institutions could hold securities as long as those positions were financed with very short-term debt—debt that had

less than a year before maturity. Ostensibly these were independent vehicles, but as banks began to fill them up with mortgage-backed securities, the question was whether banks could afford to let them collapse.

Swap: Earliest of the derivatives; contracts between two parties (see counterparty) enabling them to swap one risk for another. Swaps made their debut in the interest rate (bond) markets and the currency exchange markets amid tremendous volatility of the 1980s. A company with floating-rate debt and fearful of a jump in interest rates could pay a fee to a banker who would structure a "swap" enabling them to exchange that floating rate for fixed debt. In exchange for some kind of premium, the counterparty would take on the interest rate risk. The counterparty (often a financial institution) would then seek to hedge (or offset) its own risk associated with that trade.

Synthetic security: An index is a synthetic structure—it is designed to represent something else. You can't buy the S&P 500 Index, for instance, although you can buy one share of each of the five hundred companies. Similarly, a synthetic CDO is a CDO designed and structured to mimic the performance of real assets. These securities may mimic returns but offer features that aren't available to investors in those underlying assets. Most synthetic securities are private placements, not readily available to the average investor.

Systemic risk: The risk that the entire financial system will come tumbling down. Because it has never really occurred—although it has been prevented, sometimes narrowly, on many occasions—this risk tends to be underestimated in practice, and is hard to measure and guard against.

Tail: Imagine a bell curve, with a big bump in the middle and lines falling to be almost flat at each end. Those end points are the "tails." In most financial markets, the big bump in the middle is

where most outcomes occur—the greatest probability of a change in the price of a stock will be found here. Let's say that for 364 days of the year, a stock's price never moves more than 3 percent. That's the big bump in the middle. Over on the tail are those other moves, the outliers. Over there is the one day in a year when it trades only 1 percent, or a whopping 15 percent. The more unlikely the move, the more unprecedented, the lower its probability and the further its location out on the tail. But over time, people grew complacent about those low-probability events, or "Black Swans"—just as they were about to burst upon the market in 2008.

Too big to fail: Shorthand for the idea that some financial institutions have become simply too large and interconnected—and too vital to the economy—to collapse and file for bankruptcy without wreaking havoc on the entire financial system. Accordingly, the theory runs, the managers of these banks can be tempted to take on more risk simply because they believe that the government will be forced to bail them out if they hit the rocks. (See moral hazard.)

Tranche: Literally, a slice; in practice it refers to a slice of a deal, whether a new financing, a CDO, or a loan, etc. A tranche tends to have specific risk and return characteristics relative to other tranches of the same transaction.

Transparency: The degree to which risk and return can be easily gauged and information about an investment can be readily obtained. The large-cap U.S. stock market is said to be highly transparent.

Underwriting: The process of bringing a security to market.

Underwriting fees: The percentage of the total sum raised in the sale of stock, bonds, or other securities that is allocated to the underwriters as a fee for their efforts. This varies with the size of

the transaction and its difficulty. Stock transactions of little-known startup companies typically command a 7 percent fee; someone selling bonds for a Fortune 500 company will get significantly less than 1 percent. Junk bond fees might fall somewhere in the middle.

Value/Valuation: It's always in the eyes of the beholder. A value investor is in quest of a stock or bond that is trading beneath what she believes to be its actual value and that she believes will rise in price until the valuation is "fair."

VaR: Value at Risk—Can be used by buyers to convince themselves that they were taking much less risk than was in fact the case; it is a backward-looking measure. Built around probability theory, the goal was to look across the entire panoply of a financial institution's operations and come up with a single number reflecting how much it might lose over a defined period (typically the next twenty-four hours) with a certain probability or level of certainty, say 95 percent. Bank executives viewed the number as a kind of worst-case scenario; a jump in VaR would serve as a warning signal that the bank was suddenly risking more of its capital. VaR was alluring (it could measure risk in every kind of financial asset by looking at its pricing history, however complex or straightforward) but also deceptive, because it relied on history and put a lot of emphasis on more recent history. (It also ignored the risk of what would happen the remaining 5 percent of the time; see tail, Black Swan.) So the further back in time that extreme price swings receded, the less likely they were to affect the VaR calculation. The weaknesses of relying on simplistic VaR measures became clear in 2008—often too late. VaR's greatest utility was, and remains, as a starting point for a broader discussion of risk.

Venture capital: Startup capital for fledgling companies where the potential risk of failure greatly outstrips the prospects for success. Perhaps 20 percent of a venture fund's portfolio companies will

generate big returns; another 10 percent may go belly-up. In return for much-needed capital, validation in the eyes of the market, help with the business plan, and marketing, etc., the VC investor gets great terms and can have a lot of say in how the business is run.

Vulture investor: An investor who likes to pick over the carcass of a truly dreadful investment, in hopes of finding a smidgen of value.

Yield: A function of a security's price and whatever kind of income stream (coupon or dividend) it offers the investor. For instance, buying a bond that has a 7 percent annual interest payment at $100 or at $95 will give an investor two different yields; the latter investor pays less and thus collects a higher yield. Price and yield always move in opposite directions, and yield is a function of how much an investor values a preset rate of return.

ACKNOWLEDGMENTS

Writing a book is never a solo venture, even though it may feel like it some days. My greatest thanks have to go to my editor, John Mahaney, for spotting the potential in an unconventional kind of book, one that looked at the concept of Wall Street. When the dramatic events of the summer and autumn of 2008 forced me to rethink the project from soup to nuts, John was unfailingly and amazingly patient and supportive—just as later he was there to prod me to deliver something better whenever I needed it. This book would never have seen the light of day without the efforts of my intrepid agent, Giles Anderson. I was astonished to learn that some agents consider their job done when the contract is signed; Giles was always there for me to lean on or bounce ideas off of through the whole process.

I wish it were possible for me to thank by name all those who have toiled on Wall Street—some for decades—who made this book possible by sharing with me their experiences and reflections. Unfortunately, most of them would be furious if I did, and perhaps that is one of the saddest comments about Wall Street as it functions today: the inability to be self-critical in public.

Paul Bennett was an admirable research assistant, scrambling around in search of esoteric facts and figures. The folks at Dealogic LLC never batted an eyelash at the most extraordinary data requests; a special thank-you is owed to Dimitri Kiriazov, who has since left the firm. The idea for this book—and the awareness of the magnitude of the gap that exists between Wall Street and "Main Street"—grew out of the series of classes I taught for Media Bistro: my thanks to Carmen Scheidel and her group for giving me that opportunity. Rachel Elson, the queen of the headlines, spent an entire dinner (and consumed an entire paper tablecloth) trying to come up with just the right headline for the book. An eclectic group of individuals helped me find an even more diverse group of Wall Streeters, past and present, to talk to: my thanks, in particular,

to Tony Guernsey, Heather Fontaine, Jonathan Cunningham, Bill Thompson, Aline Sullivan, Steve Martiros, Mary Sedarat, and Laura Congleton. Thanks to the folks at Intelligence Squared for access to the St. Patrick's Day 2009 debate on Wall Street—and the transcript. Bob Kurucza tried to keep me from wandering too far afield in my speculations about who's to blame and what happens next; I owe him thanks for serving as a sounding board. Without the technical assistance from Chris Manigan, I don't think I would ever have completed the manuscript.

An incredible number of friends, family members, and editors have had to put up with my distraction and absences for nearly two years, from the time I began working on the project until I finally bade farewell to the galleys. Jo Rodgers at Crown kept reminding me that there is a light at the end of the tunnel; Michelle Moran, having been through all of this, convinced me that it wasn't an oncoming train. Alice Finn helped me on my way during some of the darkest days, and Elizabeth Wine's amazing cake-baking skills were always appreciated. My brother, David, came up with some smart ideas for the book's structure, while the drawings from my niece and nephews, Julie, Connor, and Jamie, were pinned up by my desk to make me smile. Special thanks to Joy Russell, Freya Kristjanson, Glenys Babcock, Bev Mazzarella, Glenn Becker, Gerit Quealy, Judith Dobrzynski, Solange de Santis, Marion Asnes, and Ron Bunn for cheering me on while never asking me the dreaded question "When will it be done?"

This book could never have been written without the help in decades past of some great editors. I'd like to thank, in particular, Mike Malloy, Barbara Donnelly Granito, Justin Schack, Dan Colarusso, Phil Roosevelt, and Anita Peltonen for demanding the best work I could deliver. Much of any credit for this book belongs to them and the other editors I've worked with; any flaws and shortcomings are, of course, my own responsibility.

INTRODUCTION
13 Bankers

> My administration is the only thing between you and the pitchforks.
>
> —Barack Obama, March 27, 2009[1]

Friday, March 27, 2009, was a lovely day in Washington, D.C.—but not for the global economy. The U.S. stock market had fallen 40 percent in just seven months, while the U.S. economy had lost 4.1 million jobs.[2] Total world output was shrinking for the first time since World War II.[3]

Despite three government bailouts, Citigroup stock was trading below $3 per share, about 95 percent down from its peak; stock in Bank of America, which had received two bailouts, had lost 85 percent of its value. The public was furious at the recent news that American International Group, which had been rescued by commitments of up to $180 billion in taxpayer money, was paying $165 million in bonuses to executives and traders at the division that had nearly caused the company to collapse the previous September. The Obama administration's proposals to stop the bleeding, initially panned in February, were still receiving a lukewarm response in the press and the markets. Prominent economists were calling for certain major banks to be taken over by the government and restructured. Wall Street's way of life was under threat.

That Friday in March, thirteen bankers—the CEOs of thirteen of the country's largest financial institutions—gathered at the White House to meet with President Barack Obama.[*] "Help me help you," the president urged the group. Meeting with reporters later, they toed the party line. White House press secretary Robert Gibbs summarized the president's message: "Everybody has to pitch in. We're all in this together." "I'm of the feeling that we're all in this together," echoed Vikram Pandit, CEO of Citigroup. Wells Fargo CEO John Stumpf repeated the mantra: "The basic message is, we're all in this together."[5]

What did that mean, "we're all in this together"? It was clear that the thirteen bankers needed the government. Only massive government intervention, in the form of direct investments of taxpayer money, government guarantees for multiple markets, practically unlimited emergency lending by the Federal Reserve, and historically low interest rates, had prevented their banks from following Bear Stearns, Lehman Brothers, Merrill Lynch, Washington Mutual, and Wachovia into bankruptcy or acquisition in extremis. But why did the government need the bankers?

Any modern economy needs a financial system, not only to process payments, but also to transform savings in one part of the economy into productive investment in another part of the economy. However, the Obama administration had decided, like the George W. Bush and Bill Clinton administrations before it, that it needed *this* financial system—a system dominated by the thirteen bankers who came to the White House in March. Their banks used huge balance sheets to place bets in brand-new financial markets, stirring together complex derivatives with exotic mortgages in a toxic brew that ultimately poisoned the global economy. In the process, they grew so large that their potential failure threatened the stability of the entire system, giving them a unique degree of leverage over the government. Despite the central role of these banks in causing the financial crisis and the recession, Barack Obama and his advisers decided that these were the banks the country's economic prosperity depended on. And so they dug in to defend Wall Street against the popular anger that was sweeping the country—the "pitchforks" that Obama referred to in the March 27 meeting.[6]

To his credit, Obama was trying to take advantage of the Wall Street crisis to wring concessions from the bankers—notably, he wanted them to scale back the bonuses that enraged the public and to support his administration's plan to overhaul regulation of the financial system. But as the spring and summer wore on, it became increasingly clear that he had failed to win their cooperation. As the megabanks, led by JPMorgan Chase and Goldman Sachs, reported record or near-record profits (and matching bonus pools), the industry rolled out its heavy artillery to fight the relatively moderate reforms proposed by the administration, taking particular aim at the measures intended to protect unwary consumers from being blown up by expensive and risky mortgages, credit cards, and bank accounts. In September, when Obama gave a major speech at Federal Hall in New York asking Wall Street to support significant reforms, not a single CEO of a major bank bothered to show up.[7] If Wall Street was going to change, Obama would have to use (political) force.

Why did this happen? Why did even the near-collapse of the financial system, and its desperate rescue by two reluctant administrations, fail to give the government any real leverage over the major banks?

By March 2009, the Wall Street banks were not just any interest group. Over the past thirty years, they had become one of the wealthiest industries in the history of the American economy, and one of the most powerful political forces in Washington. Financial sector money poured into the campaign war chests of congressional representatives. Investment bankers and their allies assumed top positions in the White House and the Treasury Department. Most important, as banking became more

complicated, more prestigious, and more lucrative, the *ideology* of Wall Street—that unfettered innovation and unregulated financial markets were good for America and the world—became the consensus position in Washington on both sides of the political aisle. Campaign contributions and the revolving door between the private sector and government service gave Wall Street banks influence in Washington, but their ultimate victory lay in shifting the conventional wisdom in their favor, to the point where their lobbyists' talking points seemed self-evident to congressmen and administration officials. Of course, when cracks appeared in the consensus, such as in the aftermath of the financial crisis, the banks could still roll out their conventional weaponry—campaign money and lobbyists; but because of their ideological power, many of their battles were won in advance.

The political influence of Wall Street helped create the laissez-faire environment in which the big banks became bigger and riskier, until by 2008 the threat of their failure could hold the rest of the economy hostage. That political influence also meant that when the government did rescue the financial system, it did so on terms that were favorable to the banks. What "we're all in this together" really meant was that the major banks were already entrenched at the heart of the political system, and the government had decided it needed the banks at least as much as the banks needed the government. So long as the political establishment remained captive to the idea that America needs big, sophisticated, risk-seeking, highly profitable banks, they had the upper hand in any negotiation. Politicians may come and go, but Goldman Sachs remains.

The Wall Street banks are the new American oligarchy—a group that gains political power because of its economic power, and then uses that political power for its own benefit. Runaway profits and bonuses in the financial sector were transmuted into political power through campaign contributions and the attraction of the revolving door. But those profits and bonuses also bolstered the credibility and influence of Wall Street; in an era of free market capitalism triumphant, an industry that was making so much money had to be good, and people who were making so much money had to know what they were talking about. Money and ideology were mutually reinforcing.

This is not the first time that a powerful economic elite has risen to political prominence. In the late nineteenth century, the giant industrial trusts—many of them financed by banker and industrialist J. P. Morgan—dominated the U.S. economy with the support of their allies in Washington, until President Theodore Roosevelt first used the antitrust laws to break them up. Even earlier, at the dawn of the republic, Thomas Jefferson warned against the political threat posed by the Bank of the United States.

In the United States, we like to think that oligarchies are a problem that other countries have. The term came into prominence with the consolidation of wealth and power by a handful of Russian businessmen in the mid-1990s; it applies equally well to other emerging market countries where well-connected business leaders trade cash and political support for favors from the government. But the fact that our American oligarchy operates not by bribery or blackmail, but by the soft power of access and ideology, makes it no less powerful. We may have the most advanced political system in the world, but we also have its most advanced oligarchy.

In 1998, the United States was in the seventh year of an economic boom. Inflation was holding steady between 2 and 3 percent, kept down by the twin forces of technology and globalization. Alan Greenspan, probably the most respected economist in the world, thought the latest technology revolution would allow sustained economic growth with low inflation: "Computer and telecommunication based technologies are truly revolutionizing the way we produce goods and services. This has imparted a substantially increased degree of flexibility into the workplace, which in conjunction with just-in-time inventory strategies and increased availability of products from around the world, has kept costs in check through increased productivity."[8] Prospects for the American economy had rarely seemed better.

But Brooksley Born was worried.[9] She was head of the Commodity Futures Trading Commission (CFTC), the agency responsible for financial contracts known as derivatives. In particular, she was worried about the fast-growing, lightly regulated market for over-the-counter (OTC) derivatives—customized contracts in which two parties placed bets on the movement of prices for other assets, such as currencies, stocks, or bonds. Although Born's agency had jurisdiction over certain derivatives that were traded on exchanges, it was unclear if anyone had the authority to oversee the booming market for custom derivatives.

In 1998, derivatives were the hottest frontier of the financial services industry. Traders and salesmen would boast about "ripping the face off" their clients—structuring and selling complicated deals that clients did not understand but that generated huge profits for the bank that was brokering the trade.[10] Even if the business might be bad for their clients, the top Wall Street banks could not resist, because their derivatives desks were generating ever-increasing shares of their profits while putting up little of the banks' own capital.[*] The global market for custom derivatives had grown to over $70 trillion in face value (and over $2.5 trillion in market value)[†] from almost nothing a decade before.[11]

The derivatives industry had fought off the threat of regulation once before. In 1994, major losses on derivatives trades made by Orange County, California, and Procter & Gamble and other companies led to a congressional investigation and numerous lawsuits. The suits uncovered, among other things, that derivatives salesmen were lying to clients, and uncovered the iconic

quote of the era, made by a Bankers Trust employee: "Lure people into that calm and then just totally f____'em."[12] Facing potential congressional legislation, the industry and its lobbying group fought back, aided by its friends within the government. The threat of regulation was averted, and the industry went back to inventing ever more complex derivatives to maintain its profit margins. By 1997, the derivatives business even had the protection of Greenspan, who said: "[T]he need for U.S. government regulation of derivatives instruments and markets should be carefully re-examined. The application of the Commodity Exchange Act to off-exchange transactions between institutions seems wholly unnecessary—private market regulation appears to be achieving public policy objectives quite effectively and efficiently."[13] In other words, the government should keep its hands off the derivatives market, and society would benefit.

But Born was not convinced. She worried that lack of oversight allowed the proliferation of fraud, and lack of transparency made it difficult to see what risks might be building in this metastasizing sector. She proposed to issue a "concept paper" that would raise the question of whether derivatives regulation should be strengthened. Even this step provoked furious opposition, not only from Wall Street but also from the economic heavyweights of the federal government—Greenspan, Treasury Secretary (and former Goldman Sachs chair) Robert Rubin, and Deputy Treasury Secretary Larry Summers. At one point, Summers placed a call to Born. As recalled by Michael Greenberger, one of Born's lieutenants, Summers said, "I have thirteen bankers in my office, and they say if you go forward with this you will cause the worst financial crisis since World War II."[14]

Ultimately, Summers, Rubin, Greenspan, and the financial industry won. Born issued the concept paper in May, which did not cause a financial crisis. But Congress responded in October by passing a moratorium prohibiting her agency from regulating custom derivatives.[15] In 1999, the President's Working Group on Financial Markets—including Summers, Greenspan, SEC chair Arthur Levitt, and new CFTC chair William Rainer—recommended that custom derivatives be exempted from federal regulation. This recommendation became part of the Commodity Futures Modernization Act, which President Clinton signed into law in December 2000.

We don't know which thirteen bankers were meeting with the deputy treasury secretary when he called Brooksley Born; nor do we know if it was actually twelve or fourteen bankers, or if they were in his office at the time, or if Summers was actually convinced by them—more likely he came to his own conclusions, which happened to agree with theirs. (Summers did not comment for the *Washington Post* story that reported the phone call.) Nor does it matter.

What we do know is that by 1998, when it came to questions of modern finance and financial regulation, Wall Street executives and lobbyists had many sympathetic ears in government, and important policymakers were inclined to follow their advice. Finance had become a complex, highly quantitative field that only the Wall Street bankers and their backers in academia (including multiple Nobel Prize winners) had mastered, and people who questioned them could be dismissed as ignorant Luddites. No conspiracy was necessary. Even Summers, a brilliant and notoriously skeptical academic economist (later to become treasury secretary and eventually President Obama's chief economic counselor), was won over by the siren song of financial innovation and deregulation. By 1998, it was part of the worldview of the Washington elite that what was good for Wall Street was good for America.

The aftermath is well known. Although Born's concept paper did not cause a financial crisis, the failure to regulate not only derivatives, but many other financial innovations, made possible a decade-long financial frenzy that ultimately created the worst financial crisis and deepest recession the world has endured since World War II.

Free from the threat of regulation, OTC derivatives grew to over $680 trillion in face value and over $20 trillion in market value by 2008. Credit default swaps, which were too rare to be measured in 1998, grew to over $50 trillion in face value and over $3 trillion in market value by 2008, contributing to the inflation of the housing bubble;[16] when that bubble burst, the collapse in the value of securities based on the housing market triggered the financial crisis. The U.S. economy contracted by 4 percent, financial institutions took over one trillion dollars of losses, and the United States and other governments bailed out their banking sectors with rescue packages worth either hundreds of billions or trillions of dollars, depending on how you count them.[17]

Brooksley Born was defeated by the new financial oligarchy, symbolized by the thirteen bank CEOs who gathered at the White House in March 2009 and the "thirteen bankers" who lobbied Larry Summers in 1998. The major banks gained the wealth and prestige necessary to enter the halls of power and sway the opinions of the political establishment, and then cashed in that influence for policies—of which derivatives nonregulation was only one example—that helped them double and redouble their wealth while bringing the economy to the edge of a cliff, from which it had to be pulled back with taxpayer money.

The choices the federal government made in rescuing the banking sector in 2008 and 2009 also have significant implications for American society and the global economy today. Not only did the government choose to rescue the financial system—a decision few would question—but it chose to do so by extending a blank check to the largest, most powerful banks in their moment of greatest need. The government chose *not* to impose conditions that could reform the industry or even to replace the management of large failed banks. It chose to stick with the bankers it had.

In the dark days of late 2008—when Lehman Brothers vanished, Merrill Lynch was acquired, AIG was taken over by the government, Washington Mutual and Wachovia collapsed, Goldman Sachs and Morgan Stanley fled for safety by morphing into "bank holding companies," and Citigroup and Bank of America teetered on the edge before being bailed out—the conventional wisdom was that the financial crisis spelled the end of an era of excessive risk-taking and fabulous profits. Instead, we can now see that the largest, most powerful banks came out of the crisis even larger and more powerful. When Wall Street was on its knees, Washington came to its rescue—not because of personal favors to a handful of powerful bankers, but because of a belief in a certain kind of financial sector so strong that not even the ugly revelations of the financial crisis could uproot it.

That belief was reinforced by the fact that, when the crisis hit, both the Bush and Obama administrations were largely manned by people who either came from Wall Street or had put in place the policies favored by Wall Street. Because of these long-term relationships between Wall Street and Washington, there was little serious consideration during the crisis of the possibility that a different kind of financial system might be possible—despite the exhortations of prominent economists such as Paul Krugman, Joseph Stiglitz, and many others. There was no serious attempt to break up the big banks or reform financial regulation while it was possible—when the banks were weak, at the height of the crisis. Reform was put off until after the most powerful banks had grown even bigger, returned to profitability, and regained their political clout. This strategy ran counter to the approach the U.S. Treasury Department had honed during emerging market financial crises in the 1990s, when leading officials urged crisis-stricken countries to address structural problems quickly and directly.

As we write this, Congress looks likely to adopt some type of banking reform, but it is unlikely to have much bite. The measures proposed by the Obama administration placed some new constraints on Wall Street, but left intact the preeminence and power of a handful of megabanks; and even these proposals faced opposition from the financial lobby on Capitol Hill. The reform bill will probably bring about some improvements, such as better protection for consumers against abusive practices by financial institutions. But the core problem—massive, powerful banks that are both "too big to fail" and powerful enough to tilt the political landscape in their favor—will remain as Wall Street returns to business as usual.

By all appearances, the major banks—at least the ones that survived intact—were the big winners of the financial crisis. JPMorgan Chase, Bank of America, and Wells Fargo bought up failing rivals to become even bigger. The largest banks increased their market shares in everything from issuing credit cards to issuing new stock for companies.[18] Goldman Sachs reported record profits and, through September 2009, had already set aside over $500,000 per employee for compensation.[19] Lloyd Blankfein, CEO of Goldman Sachs, was named Person of the Year by the *Financial Times*.[20]

The implications for America and the world are clear. Our big banks have only gotten bigger. In 1983, Citibank, America's largest bank, had $114 billion in assets, or 3.2 percent of U.S. gross domestic product (GDP, the most common measure of the size of an economy). By 2007, nine financial institutions were bigger relative to the U.S. economy than Citibank had been in 1983.[21] At the time of the White House meeting, Bank of America's assets were 16.4 percent of GDP, followed by JPMorgan Chase at 14.7 percent and Citigroup at 12.9 percent.[22] A vague expectation that the government would bail them out in a crisis has been transformed into a virtual certainty, lowering their funding costs relative to their smaller competitors. The incentive structures created by high leverage (shifting risk from shareholders and employees onto creditors and, ultimately, taxpayers) and huge one-sided bonuses (great in good years and good in bad years) have not changed. The basic, massive subsidy scheme remains unchanged: when times are good, the banks keep the upside as executive and trader compensation; when times are bad and potential crisis looms, the government picks up the bill.

If the basic conditions of the financial system are the same, then the outcome will be the same, even if the details differ. The conditions that created the financial crisis and global recession of 2007–2009 will bring about another crisis, sooner or later. Like the last crisis, the next one will cause millions of people to lose their jobs, houses, or educational opportunities; it will require a large transfer of wealth from taxpayers to the financial sector; and it will increase government debt, requiring higher taxes in the future. The effects of the next meltdown could be milder than the last one; but with a banking system that is even more highly concentrated and that has a rock-solid government guarantee in place, they could also be worse.

The alternative is to reform the financial system now, to put in place a modern analog to the banking regulations of the 1930s that protected the financial system well for over fifty years. A central pillar of this reform must be breaking up the megabanks that dominate our financial system and have the ability to hold our entire economy hostage. This is the challenge that faces the Obama administration today. It is not a question of finance or economics. It is ultimately a question of politics—whether the long march of Wall Street on Washington can be halted and reversed. Given the close financial, personal, and ideological ties between these two centers of power, that will not happen overnight.

We have been here before. The confrontation between concentrated financial power and democratically elected government is as old as the American republic. History shows that finance can be made safe again. But it will be quite a fight.

* The CEOs and their banks were Ken Chenault, American Express; Ken Lewis, Bank of America; Robert Kelly, Bank of New York Mellon; Vikram Pandit, Citigroup; John Koskinen, Freddie Mac; Lloyd Blankfein, Goldman Sachs; Jamie Dimon, JPMorgan Chase; John Mack, Morgan Stanley; Rick Waddell, Northern Trust; James Rohr, PNC; Ronald

Logue, State Street; Richard Davis, US Bank; and John Stumpf, Wells Fargo. There were also two representatives of industry organizations at the meeting.[4]

* Because the accounting treatment of derivatives was unclear, the amount of capital that banks had to set aside for their derivatives positions was generally disproportionately low compared to the amount of risk they were taking on. Because they could generate higher profits with less capital, their "return on equity" was higher.

† Derivatives are essentially zero-sum transactions. The face value, or notional value, of a derivative is the basis on which the value of the transaction is calculated. For example, in an interest rate swap, the payments made by the two parties are calculated as interest rates (percentages) on the notional value; the amount of money that changes hands is much lower than the notional value. The market value of a derivative contract is calculated by the Bank for International Settlements as the current value of the contract to the party that is "in the money"—in other words, the amount of money that would change hands in order to close out the contract at this moment.

THOMAS JEFFERSON AND THE FINANCIAL ARISTOCRACY

> Great corporations exist only because they are created and safeguarded by our institutions; and it is therefore our right and our duty to see that they work in harmony with these institutions.
>
> —Theodore Roosevelt, State of the Union message, December 3, 1901[1]

Suspicion of large, powerful banks is as old as the United States, dating back at least to Thomas Jefferson—author of the Declaration of Independence, secretary of state under President George Washington, third president of the United States, and staunch proponent of individual liberty. Although Jefferson is one of the most revered founders of the republic, according to conventional wisdom he was not much of an economist.[2] Jefferson believed in an agrarian society with decentralized institutions and limited political and economic power. He was deeply suspicious of banks and criticized them in vitriolic terms, writing, "I sincerely believe, with you, that banking institutions are more dangerous than standing armies."[3] In a letter to James Madison, Jefferson even suggested, quite seriously, that anyone who cooperated with a federally chartered bank was guilty of treason and should be executed.[4]

The United States, however, did not turn out to be a decentralized agrarian society, in part because finance, commerce, and industry have also had their supporters throughout American history. Jefferson was opposed by Alexander Hamilton, Washington's secretary of the treasury, who favored a stronger federal government that actively supported economic development. In particular, Hamilton believed that the government should ensure that sufficient credit was available to fund economic development and transform America into a prosperous, entrepreneurial country. This would require the introduction of modern forms of finance opposed by Jefferson. This tension between Jefferson and Hamilton has endured to the present day.

Hamilton favored a publicly chartered (though largely privately owned) bank modeled on the Bank of England, which would manage the federal government's money and provide an important source of credit to the government and the economy. Legislation to create the (First) Bank of the United States passed Congress easily in 1791. Jefferson lobbied hard for President Washington to veto it, however, arguing that the power to charter a bank was not expressly granted to Congress by the Constitution and therefore remained with the states under the Tenth Amendment ("The powers not delegated to the United States by the Constitution, nor prohibited by it to the States, are reserved to the States respectively, or to the people").* Washington went so far as to request that James Madison (principal author of the Constitution and the Bill of Rights) draft a veto, but he also allowed Hamilton the opportunity to respond.[5] Hamilton's fifteen-thousand-word memo, largely written at the last minute, convinced Washington that a federal bank was a "necessary and proper" application of Congress's power and responsibility to promote fiscal stability and regulate trade by supporting the broader commercial system.[6] The president signed the legislation without allowing Jefferson a rebuttal.[7]

After all the furor and rhetoric, the immediate historical aftermath was rather dull. The Bank of the United States functioned broadly as advertised by Hamilton, managing the government's incoming revenues and outgoing payments and facilitating payments across an otherwise small-scale and fragmented financial system.[8] It won over many supporters, although not Jefferson and Madison (at least at first), who formed the Democratic-Republican Party to oppose Hamilton's Federalist Party, in part because of the Bank of the United States.

When it came to the basic economic issues, Hamilton was right. Economic development in the early United States depended heavily on the creation of a well-functioning financial system, as shown by modern scholars such as Richard Sylla and Peter Rousseau.[9] The United States in the 1780s "lacked nearly all the elements of a modern financial system, [but] by the 1820s had a financial system that was innovative, large and perhaps the equal of any in the world."[10] This was due not only to the Bank of the United States, but also to other financial reforms implemented by Hamilton, such as his careful management of cash flows into and out of the Treasury while keeping money on deposit with "approved banks," as well as his highly influential reports to Congress on credit and manufacturing.[11] Hamilton successfully argued that the federal government should assume the debts incurred by the individual states during the American Revolution, thereby setting the valuable precedent that the United States would always pay its debts.[12] In Ron Chernow's words, "Hamilton did not create America's market economy so much as foster the culture and legal setting in which it flourished."[13] The result was a stable and relatively favorable environment for banking. The United States had only three banks in 1789, but twenty-eight banks were chartered in the 1790s and another seventy-three in the first decade of the 1800s.[14] Bank shareholders had limited liability, a real innovation at the time (in England before the 1850s, only the Bank of England had limited liability) that helped attract entrepreneurs and money.[15] By 1825, when the United States and the United Kingdom had roughly the same population (11.1 million and 12.9 million,

respectively), the United States had nearly 2.5 times the amount of bank capital as the United Kingdom.[16]

The United States also rapidly developed a healthy equity market that was able to attract capital from around the world. Already by 1803, more than half of all U.S. securities were held by European investors.[17] By 1825, there were 232 listed securities in the United States (in New York, Philadelphia, Boston, Baltimore, and Charleston combined), approaching the 320 securities listed in England, and the level of equity market capitalization was similar in both countries. Many of the companies listed in American stock markets represented the leading sectors of the modern economy, including insurance, transportation, utilities, and manufacturing.[18] The abundance of both bank capital and equity financing meant that there was plenty of money available to invest in new and expanding businesses—initially concentrated in New England, but soon spreading to the rest of the country.[19]

A modern financial system became even more important with the spread of the Industrial Revolution early in the nineteenth century, which neither Jefferson nor even Hamilton foresaw. At the time of their debates, the Industrial Revolution was decidedly small-scale and largely confined to England. But the progressive application of technology to the production of goods would vastly raise the potential output of the American economy and permanently change its place in the world. Because industrialization required investments in new technology, it also required credit. Jefferson's small-scale farms may have represented a democratic political ideal (at least for those fortunate enough to own those farms and not be slaves working on them), but long-run prosperity required large-scale commerce and industry, both of which required banks. In retrospect, Jefferson's economic positions seem either cranky and uninformed or motivated by his distaste for the Northern commercial interests that he correctly predicted would benefit from a strong central government and eventually undermine Southern plantation (and slave) owners such as himself.[20]

But while Hamilton may have been right about the economics, that was not Jefferson's primary concern. His fear of large financial institutions had nothing to do with the efficient allocation of capital and everything to do with power. Jefferson correctly discerned that banks' crucial economic functions—mediating financial transactions and creating and managing the supply of credit—could give them both economic and political power. In the 1790s, Jefferson was particularly worried that the Bank of the United States could gain leverage over the federal government as its major creditor and payment agent, and could pick economic winners and losers through its decisions to grant or withhold credit. Over the past two hundred years, financial institutions and markets have only become more intertwined with the day-to-day functioning of the economy, to the point where large companies depend on the short-term credit they use to manage their cash flow as much as they depend on electricity. In Jefferson's eyes, the increasing importance of finance to society would only give banks even more power—power that could be used to benefit the bankers themselves, or in extreme cases could even threaten to undermine American democracy.

In matters of economic policy, we tend as a nation to lean toward Hamilton. As President Calvin Coolidge said in 1925, "[The American people] are profoundly concerned with producing, buying, selling, investing and prospering in the world."[21] And for most of American history, that has served us relatively well. The United States would not have the largest economy in the world without a financial sector that has, most of the time, funneled capital toward the investments in new technology and processes that are critical to long-term productivity growth.

However, our Hamiltonian inclinations—to seek out efficiency, to celebrate bigness, and to look favorably on anything that makes money—have been kept at least partially in check by the legacy of Jefferson. Although Jefferson lost the battle over the Bank of the United States (and his worst fears did not materialize), the cause of restraining concentrated economic or financial power was taken up by three of his most important successors. In the 1830s, Andrew Jackson's showdown with the Second Bank of the United States set back the development of a concentrated financial sector. At the beginning of the twentieth century, the crusade against the industrial trusts begun by Theodore Roosevelt ultimately left intact the powerful private banks symbolized by J.P. Morgan; but during the Great Depression of the 1930s, Franklin Delano Roosevelt was finally able to break up the largest banks and constrain their risky activities. While they did not achieve all of their aims, the Jeffersonian tradition represented by these presidents has served as a counterweight to Hamilton's influence, helping prevent a powerful and unfettered financial system from undermining broader prosperity. The American financial system has oscillated between concentration and fragmentation; but over the long term, it helped give us unrivaled prosperity without undermining our democratic system—at least not yet. Today, as we face the largest and most concentrated financial sector in our nation's history, Jefferson's legacy again demands our attention.

JEFFERSON'S REVENGE

Jefferson's fear of big banks was something close to an obsession for the seventh president of the United States, Andrew Jackson. "Old Hickory," like Jefferson, favored the ideal of an agrarian republic and distrusted big-city bankers.[22] Just as important, he believed in presidential power, and he saw a major national bank as a rival that needed to be dealt with.

After its charter expired in 1811, legislation to recharter the Bank of the United States narrowly failed. However, the economic dislocation caused by the War of 1812 and the resulting chaos in the financial system convinced politicians of the need for a national bank. Congress passed legislation creating the Second Bank of the United States, which was signed by President James Madison, and the bank went into operation with a twenty-year charter in 1816.[23]

By the time Jackson was elected president in 1828, the Second Bank functioned as an "important administrative agency of the government"[24]—regulating the money supply, handling the day-to-day financial operations of the U.S. government, issuing bank notes, and providing credit for both federal authorities and private sector clients (including prominent politicians). Under the management of Nicholas Biddle, it supported the development of the American capital markets and helped coordinate a banking system that primarily operated at the state or local level.[25]

Jackson, however, opposed the Second Bank on both economic and political grounds. He hated paper money and believed only in the hardest of hard money—gold and silver. Paper money, he thought, allowed banks and bankers to distort the economy at the expense of common people. In addition, the Second Bank's monopoly over government finances gave Biddle and his friends power (and profits) that, he felt, rightfully belonged to the executive branch. The president was particularly enraged that Biddle used his economic power to curry favor with Congress, influencing elected representatives to support his aims; almost every prominent person supporting Biddle was also substantially in his debt (including some of the leading politicians of the day, such as Daniel Webster and Henry Clay).[26] As Jackson's secretary Nicholas Trist put it, echoing Jefferson, "Independently of its misdeeds, the mere *power,*—the bare existence of such a power—is a thing irreconcilable with the nature and spirit of our institutions."[27]

The "Bank War" began when Biddle and his ally, Henry Clay, attempted to renew the Second Bank's charter in 1832, four years before it expired, in part to create a political issue that Clay could use in his campaign to become president.[28] In order to gain support, Biddle directed the Bank to expand its lending in a bid for popularity.[29] Congress voted to renew the Bank's charter, but Jackson vetoed the renewal. His veto message mixed together a rebuke to the Supreme Court (which had finally resolved the Jefferson-Hamilton debate over the constitutionality of the Bank of the United States in favor of Hamilton), an attack on paper money ("Congress have established a mint to coin money.… The money so coined, with its value so regulated, and such foreign coins as Congress may adopt are the only currency known to the Constitution"), a defense of states' rights, and a swipe at the economic elites ("It is to be regretted that the rich and powerful too often bend the acts of government to their selfish purposes.")[30] In private, Jackson was more personal: "The Bank," he said to Martin Van Buren (his running mate in 1832), "is trying to kill me, *but I will kill it*."[31] The veto held up when Jackson defeated Clay in the 1832 presidential election. Biddle did not go quietly, however. When Jackson began transferring the federal government's deposits out of the Second Bank to his favored "pet banks," the Second Bank demanded payment on bills issued by state banks and reduced its loans by over $5 million, contracting the money supply and causing interest rates to double to 12 percent. Biddle hoped, by damaging the economy, to stir up opposition to Jackson; in the process, he showed that Jackson had not been wrong to fear the power of a major bank to distort the economy for its own purposes.[32]

Eliminating the most efficient commercial bank in the United States was probably not a textbook example of sound macroeconomic management, especially according to today's textbook. Jackson's veto most likely slowed the development of an integrated payments and credit system such as those seen in more advanced parts of Europe.[33] Without a major national bank or a central bank with the ability to stabilize the financial system, the U.S. economy also suffered through severe business cycles through the rest of the nineteenth century.

However, the primary importance of the Bank War was not economic, but political.[34] Although Jackson's economic grounds for opposing a new charter may have been weak, the Second Bank's behavior showed the political danger presented by a powerful private bank. Biddle was able to bribe, cajole, or otherwise pressure congressmen into taking his side against the president. Not all of the Bank's supporters were in it for the money. But as the war raged, Daniel Webster wrote to Biddle, "I believe my retainer has not been renewed or *refreshed* as usual. If it be wished that my relation to the Bank should be continued, it may be well to send me the usual retainers."[35] More ominously, at least as interpreted by Jackson's supporters, Biddle had attempted to hold the economy hostage to his political ends, first expanding credit in order to gain political support and then withholding it (and triggering a recession) in order to punish Jackson.[36] This was exactly what Jefferson had feared.

Both Jefferson and Jackson saw a powerful bank as a corrupting influence that could undermine the proper functioning of a democratic government. While this was not a foregone conclusion—the First Bank had lost its bid for a renewed charter in part because of its political weakness[37]—the Bank War gave a hint of the way financial power could be misused for political ends. Jefferson and Jackson did not think the government could control finance; the idea of a modern, technocratic central bank lay beyond their imagination, far in the future. Instead, they feared that powerful, privately owned financial institutions would gain disproportionate influence over the government. Given the choice between the Second Bank and no national bank at all, Jackson chose the latter. As a result, central banking developed slowly and informally in the United States, especially when compared to Europe.[38] But even with this handicap, the U.S. economy continued to innovate and grow through the nineteenth century.

Most important, Jackson's victory ensured that a powerful private bank was not able to install itself in the corridors of political power and use its privileged position to extract profits for itself, inhibit competition, and hamper broader economic development. Perhaps the United States could in any case have avoided the fate suffered during the same period by Mexico or Brazil—where a small elite controlled a concentrated banking sector, with unfortunate economic results—and by many recent emerging markets.[39] Had Jackson lost the Bank War, it is possible that the Second Bank might have gradually evolved into a modern central bank without distorting the political system to its own advantage.[40] But this was not a risk that Jackson wanted to take, and his populist prejudices against financial elites (and his desire for increased presidential power) ensured that the American financial system would err on the side of fragmentation and decentralization. Although the resulting financial system was vulnerable to macroeconomic shocks, it was generally able to supply the capital needed by a growing business sector, and it did not soon generate a small elite with a dangerous amount of economic and political power.

THE MONEY TRUST

By the late nineteenth century, however, industrialization had created a powerful economic elite that held political power at all levels, with its supporters in substantial control of the Senate, the Republican Party, and the presidency. Seventy years after Jackson, it was time for another confrontation between an independent-minded president and concentrated economic power.

Despite its decentralized financial system, nineteenth-century America had turned out to be a great place to develop new ideas and make money. Americans were among the first to invent or commercialize many new technologies that arose after 1800, building companies based on innovations in agricultural implements, canals, telecommunications, steam power, railroads, chemicals, and other industries. By the end of the nineteenth century, American companies were at the forefront of almost all of the technology-intensive industries that were making it possible to produce more and better goods with fewer and cheaper inputs.[41] Finance played a constructive supporting role during this period, providing the crucial connection or "intermediation" between savers on the one hand and people with productive investment opportunities on the other hand.[42] Capital continued to flow into productive uses even after the demise of the Second Bank.[43]

The innovations that changed the economic landscape changed the political landscape as well. Social mobility and the lack of an entrenched aristocracy meant that newly successful companies and industries could gain political representation quickly, at least when compared to European societies. New money could make its way into politics, whether legally or illegally. By the late nineteenth century, the Senate had become known as the "Millionaires' Club"; buying political support with cash was considered by many to be just an extension of normal business practices.[44]

Railroad wealth was the most prominent late-nineteenth-century example of the entrance of new money into politics. In the three decades immediately following the Civil War, America was swept by a craze for building new railroads. Fortunes were made and lost and businesses built and destroyed, while long-distance travel became much faster and hauling freight became much cheaper than ever before. The railroad barons and their industrial allies acquired great political power, coming to dominate the Senate by the turn of the century. Two of their strongest allies, Senators Mark Hanna and Nelson Aldrich, were important power brokers in the Republican Party, which controlled the White House for all but eight years from 1869 to 1913 and had a Senate majority for all but two years from 1883 to 1913. Hanna managed William McKinley's successful 1896 presidential campaign and dominated the Republican Party machine into the Theodore Roosevelt years; Aldrich was one of the most powerful men in the Senate and largely dictated its positions on government regulation of industry and banking.[45]

Political representation for rising industrial interests is preferable to ossified social structures that restrict innovation and keep new people away from the levers of power.[46] Most of the European societies that had such restrictions struggled to keep up with the Industrial Revolution and fell behind their competitors. The United States also turned out much better than Latin American countries, such as Mexico, which started at roughly similar income levels but where elites controlled concentrated banking systems; in some cases a lack of effective corporate governance led to nepotism and insider transactions that took advantage of outside shareholders.[47]

At the same time, however, the openness of the American political system has always made it possible for the current business elite to use its political power to shift the economic playing field in its favor. Any growing and profitable sector can take this route, from railroads, steel, and automobiles to defense and energy. Each of these industries has used the argument that "what's good for (fill in the blank) is good for America" in order to obtain preferential tariffs, tax breaks, or subsidies.[48]

This was the case for the new industrial trusts that emerged late in the nineteenth century.* These massive agglomerations of economic power were brought on in part by the spread of railways, which created national markets for many goods, making possible economies of scale of previously unheard-of dimensions.[49] Consolidation was also a reaction to prolonged economic downturn and perceived overcapacity in some industries. But it stemmed as well from the old-fashioned instincts of successful industrialists, who realized that combining with their competitors (at least the ones they hadn't been able to wipe out) could give them an effective monopoly, and with it the power to increase prices and profits. The rise of the trusts was a momentous development in American economic history in its own right. But it was also important because it brought concentrated financial power back onto the economic stage.

Standard Oil was an early pioneer of the trusts, followed closely by imitators in other industries. According to historian Thomas McCraw, "in the period 1897–1904 … 4,227 American firms merged into 257 combinations. By 1904, some 318 trusts … were alleged to control two-fifths of the nation's manufacturing assets."[50] The rise of the trusts depended heavily on investment bankers, who provided the money needed to buy shares and rearrange shareholdings and also offered the social glue necessary to bring disparate industrial interests together. A handful of bankers led by J. P. Morgan played a central role in this rapid transformation of the business landscape, giving Morgan an economic importance unmatched by any financier since Biddle, if not the beginning of the republic.[51] Morgan's empire handled an extraordinary share of the money flowing into American industry—as high as 40 percent of total capital raised at the beginning of the twentieth century.[52] In a lightly

regulated banking system, industrial concentration led naturally to financial concentration, and J. P. Morgan stepped forward to take the reins of the financial system.

The 1896 election of McKinley as president was welcomed by large corporate interests that feared the alternative—populist crusader William Jennings Bryan. However, they would be less happy with his second-term vice president and successor (after McKinley's assassination in September 1901), Theodore Roosevelt, who adopted "trust-busting" as a signature policy and made improved supervision of large corporations a major theme of his 1901 State of the Union address.[53] (McKinley had begun investigating the trusts, but Roosevelt was the first president to take them on directly.) Roosevelt pushed through major legislation to tighten regulation of the railroads. More important, his Department of Justice pioneered the use of the Sherman Antitrust Act of 1890 to break up large trusts, first taking aim at the Northern Securities Company, a railroad combination engineered by J. P. Morgan among others.[54] In 1904, the Supreme Court agreed with the Roosevelt administration and dissolved Northern Securities as "an illegal combination in restraint of interstate commerce."[55]

The industrial-finance barons didn't understand why Roosevelt was so worked up; J. P. Morgan's response was "If we have done anything wrong, send your man to see my man, and they can fix it up."[56] But Roosevelt, following in the tradition of Jefferson and Jackson, opposed concentrated industrial power for political reasons; he believed that dominant private interests were bad for democracy and for economic prosperity.[57] In taking on the trusts, he sought not only to obtain greater economic benefits for consumers (the prevailing modern interpretation of antitrust law), but to safeguard democracy from monied elites and maintain an economic system that was open to new ideas and new businesses. In the process, he helped change the way Americans thought about big business. As Nobel Prize–winning economist George Stigler wrote, "A careful student of the history of economics would have searched long and hard on July 2 of 1890, the day the Sherman Act was signed by President [Benjamin] Harrison, for any economist who had ever recommended the policy of actively combatting collusion or monopolization in the economy at large."[58] After Roosevelt, however, the consensus view became that antitrust law should be used to break up monopolies and prevent abuses of market power.

The Roosevelt administration's successful prosecution of antitrust cases in the courts led to more cases brought under Presidents William Howard Taft and Woodrow Wilson, including the court-ordered breakup of Standard Oil in 1911. However, these policies did little to disturb the concentration of money and power that had taken place in the financial sector in parallel with the rise of the industrial trusts. The wave of industrial concentration at the end of the nineteenth century was supposed to stabilize individual markets and cushion particular industries against overexpansion and price wars.[59] Instead, the interaction between large industrial trusts and their bankers created the backdrop for the worst financial crisis in American history to date, which brought concentrated banking power to the political forefront.

In October 1907, a routine (for the time) attempt to manipulate the price of stock in the United Copper Company by company insiders and their Wall Street banker went awry, triggering a run on banks perceived to be connected to the scheme.[60] The panic soon spread to the Knickerbocker Trust Company, one of the largest financial institutions in New York, and then to many other banks in the city. In order to raise cash quickly, banks were forced to sell whatever they could, pushing down asset prices across the board; stock prices also fell as banks cut back on loans to stockbrokers. This is a standard feature of any financial crisis.[61] Any bank has deposits that customers can withdraw immediately, while many of its loans (such as mortgages) cannot be called in on demand. As banks stop lending, borrowers are forced to liquidate assets in order to pay off their debts, reducing asset prices even further and creating more pressure on banks. In any banking system, a crisis can be rapidly magnified by this vicious cycle, sometimes called the "financial accelerator."[62]

This is the type of crisis that central banks are supposed to prevent; but thanks to Andrew Jackson's victory in the Bank War, the United States had not developed a central bank. Instead, J. P. Morgan—the man—stepped in to fill the gap. He and his team, led by Benjamin Strong, decided which banks should fail because they were irredeemably insolvent and which should be saved because they only needed some cash to get them through the panic; then they pressured other major financial institutions to join with Morgan in providing loans and deposits to threatened banks in order to ensure their survival. They were brutal in these choices, and their decisions were final. But despite J. P. Morgan's financial muscle, the private sector could not come up with sufficient funds. The only entity with enough ready money to stabilize the situation was the U.S. government, which deposited $25 million into New York banks to provide the liquidity needed to keep the financial system afloat.[63]

The Panic of 1907, which nearly brought the financial system crashing down, clearly demonstrated the risks the American economy was running with a highly concentrated industrial sector, a lightly regulated financial sector, and no central bank to backstop the financial system in a crisis. The major private banks might be able to reshape industries as they wished, but they could not be relied upon to stabilize the financial system in a crisis, especially with J. P. Morgan in his seventies. Something needed to be done. The stage was set for another political battle over the financial system.

On one side, Nelson Aldrich represented the viewpoint of the banking industry.[64] "No one can carefully study the experience of the other great commercial nations," he argued in an influential 1909 speech, "without being convinced that disastrous results of recurring financial crises have been successfully prevented by a proper organization of capital and by the adoption of wise methods of banking and of currency"—which, to him, meant a central bank that could act as a lender of last resort in a

crisis.[65] Aldrich was chair of the National Monetary Commission, founded in the aftermath of the Panic of 1907, which recommended the creation of a central banking system largely controlled by the private sector bankers themselves. The details of the planned system were hammered out at a secret meeting of top politicians and financiers at Jekyll Island off the coast of Georgia in November 1910. What these bankers wanted was a bailout mechanism that would protect the financial system in the event of a speculative crash like the Panic of 1907. They knew that a new central bank would need the political backing and financial support of the federal government, but at the same time they wanted to minimize government interference, oversight, or control.[66]

However, the Aldrich plan was politically controversial; it looked like a trick to get taxpayers to finance banks and protect them from the consequences of their risky activities. Opponents argued that the problem was a cabal of big banks that were secretly running the country. This fear was likely exaggerated, but there is no doubt that Wall Street banks played a critical role in creating the industrial trusts. In 1912, the House of Representatives, then controlled by the Democratic Party, commissioned an investigation of the "money trust" and its economic influence. (The investigation was proposed by Representative Charles Lindbergh Sr., who called the Aldrich plan a "wonderfully devised plan specifically fitted for Wall Street securing control of the world."[67]) The Pujo Committee concluded that control of credit was concentrated in the hands of a small group of Wall Street bankers, who had used their central place in the financial system to amass considerable economic power.[68] The committee report provided ammunition to Louis Brandeis, a prominent lawyer and future Supreme Court justice. Beginning with a 1913 article entitled "Our Financial Oligarchy,"[69] Brandeis spoke out strongly in favor of constraining banks. He accused the powerful investment banks of using customer deposits and other money that passed through their hands in order to take control of large companies and promote the interests of those companies. The "dominant element in our financial oligarchy is the investment banker," he concluded.[70]

Brandeis served as an adviser to the new Democratic president, Woodrow Wilson, who eventually brokered the compromise that led to the Federal Reserve Act of 1913. The final bill reduced the autonomy of the central bank and gave the government a stronger hand in its operations, notably through a Federal Reserve Board appointed by the president. However, the Federal Reserve banks were (and remain) technically private entities, and private sector banks were given the power to appoint two-thirds of their directors.[71]

While the private bankers didn't get everything they wanted in the new Federal Reserve, they did get the most important thing: an institution that could bail them out with public funds when financial crises occurred. Support by the Federal Reserve can take two broad forms: liquidity loans, where the Fed gives a bank a short-term loan that can be rolled over repeatedly; and lower interest rates, which help banks by promoting economic growth and increasing the chances that bank loans will be paid back.* These steps can mitigate individual disasters. However, the existence of government insurance against a worst-case scenario creates "moral hazard"—the incentive for banks to take on more risk in order to maximize shareholder returns—thereby laying the groundwork for the next system-wide crisis. Each emergency rescue only increases banks' confidence that they will be rescued in the future, creating a cycle of repeated booms, busts, and bailouts.[72]

In principle, in exchange for providing this insurance, the Federal Reserve would supervise the banks it was protecting, preventing them from taking too much risk. But as Brandeis spotted, echoing Jefferson, this overlooked the political dimension: "We believe that no methods of regulation ever have been or can be devised to remove the menace inherent in private monopoly and overweening commercial power."[73] Although Brandeis supported the Federal Reserve Act as a means of giving the government more control over the financial system, he would have preferred to break up large concentrations of industrial or financial power. As it turned out, the original Federal Reserve lacked the modern regulatory powers necessary to constrain the banks. In addition, the first president of the powerful Federal Reserve Bank of New York was none other than Benjamin Strong, J. P. Morgan's lieutenant and the ultimate Wall Street insider. As a result, the initial "solution" to the problem revealed by the Panic of 1907 would prove to be anything but. Instead, light regulation and cheap money would encourage banks to take on enough speculative risk to threaten the entire economy.

Theodore Roosevelt was able to curtail the growth of industrial trusts and shift the mainstream consensus so that large concentrations of economic power came to be seen by most people as dangerous to society.[74] But despite this success against the trusts, the movement to constrain the power of big banks failed, even with one of its leading advocates, Louis Brandeis, as an adviser to President Wilson. The compromise of 1913 prevented private banks from directly controlling the new central banking system. However, the Federal Reserve Act did little to constrain the banks themselves, leaving them free to engage in risky lending and generate huge economic booms that would be politically difficult to rein in. The problem that was glimpsed but not fully understood in 1907 was that when a crash finally arrived, the government would face the hard choice between letting the system collapse and bailing out the banks that had been responsible for the bubble. The original Federal Reserve, with its combination of strong private sector influence and weak regulatory authority, had the power to engineer a bailout, but not to curb the risky activities that could make one necessary.

It took only sixteen years for this flaw in the system to become catastrophically apparent. Rampant speculation in the 1920s led to the Crash of 1929, which was initially followed by a generous bailout for elite New York financial firms, and then by the repeated bungling of attempts to save the rest of the financial system. Not only did the Federal Reserve's safety net encourage excessive risk-taking by bankers; the safety net, it turned out, had gaping holes that could not be fixed in the intense pressure of a crisis. The result was the Great Depression.

Speculation on its own is not necessarily a problem. Entrepreneurs' willingness to speculate on new technologies or new ways of organizing production is a key source of growth and prosperity. However, speculation combined with large amounts of borrowed money can produce dangerous financial crises. Cheap debt makes more money available to bid on assets, driving up prices, creating vast amounts of paper wealth, and attracting new investors who borrow even more heavily so they can double their bets on a rising market. When the market turns, highly leveraged investors can be wiped out quickly, forcing them to liquidate anything that can be sold and causing asset prices to plummet. This sudden collapse in the value of almost everything can trigger widespread bank failures, corporate bankruptcies, and mass unemployment.

The 1920s were a period of significant deregulation, as Republican administrations dismantled the system of state control developed in order to fight the First World War. [75] By the time the war ended and President Warren G. Harding came to power in 1921, there was a determined effort to restore laissez-faire capitalism.[76] Harding's philosophy was "The business of America is the business of everybody in America"; his successor, Calvin Coolidge, famously said, "The chief business of the American people is business."[77] But the two people who best embodied the hands-off philosophy of the decade were Andrew Mellon, treasury secretary from 1921 to 1932, and Herbert Hoover, secretary of commerce under both Harding and Coolidge and president from 1929 to 1933. Mellon's message was clear: government should just get out of the way.[78] Regulation of private business, as espoused by Brandeis and Wilson, slipped out of fashion.[79]

The antiregulatory policies of the 1920s helped make possible a period of rampant financial speculation, driven by investment banks and closely related firms that sold and traded securities in an unregulated free-for-all. Investor protection was minimal; small investors could be lured into complex financial vehicles they didn't understand, and were offered large margin loans to leverage their positions.[80] While the market rose, everyone benefited. But the result was a stock market bubble fueled by borrowing and psychological momentum.[81] Low interest rates set by the Federal Reserve also fueled an economic boom for much of the decade and encouraged increased borrowing by companies and individuals.[82] By 1929, financial assets were at all-time highs, sustained by high levels of leverage throughout the economy. The stock market crash of October 1929 not only destroyed billions of dollars of paper wealth and wiped out many small investors; it also triggered an unprecedented wave of de-leveraging as financial institutions, companies, and investors sold anything they could in an attempt to pay off their debts, sending prices spiraling downward.[83]

The Federal Reserve could have slowed down the boom and avoided the sharp crash of 1929 if it had been willing early enough to "take away the punch bowl" (in the words of later Fed chair William McChesney Martin)[84] by raising interest rates to discourage borrowing and slow down economic growth. But this is never popular with politicians concerned about the next election, banks making large profits from the boom, or ordinary people benefiting from a strong economy. Instead, the Fed was reluctant to slow down the economy; it kept interest rates low for most of the 1920s and even lowered them in 1927, citing few signs of inflation and concerns about financial fragility outside the United States. The markets responded with a strong rally in the second half of 1927, and the Fed raised rates from 3.5 percent to 5 percent in 1928.[85] But there they stopped. Higher rates, it was feared, would choke off farmers who needed capital; they would also end the bonanza of stock price gains that benefited the financial sector and investors.[86] For similar reasons, the Fed also declined to use what regulatory powers it had to rein in debt-based investment strategies and deflate the bubble by using either moral suasion or informal arm-twisting to pressure banks to cut back on loans to finance stock purchases; this too might have ended the boom and slowed down the real economy.[87] Under considerable pressure from the banking lobby, the Fed decided to stand aside.[88]

When the crash came, however, the Fed initially rushed to the rescue. Despite internal debate, the man on the spot—George Harrison, president of the New York Fed—provided liquidity to troubled institutions; "I am ready to provide all the reserve funds that may be needed," he told bankers, urging them to lend to troubled brokers.[89] By the fall of 1930, Harrison could be proud that despite a 40 percent fall in the stock market, not a single major bank had failed. The Aldrich bailout mechanism seemed to work. Instead of J. P. Morgan stepping in to stop the Panic of 1907, this time the Federal Reserve answered the call.[90] And yet the United States, and the world, still experienced the Great Depression.

For the last seventy years there has been heated debate over whether the Fed could have prevented the financial crisis of 1929 from evolving into the Great Depression, or at least limited its impact through more assertive action. A leading view, advanced by Milton Friedman and Anna Schwartz and subscribed to (in amended form) by current Fed chair Ben Bernanke, is

that a spreading bank panic in the early 1930s caused a severe contraction of the money supply and credit, producing the Great Depression. If the Fed had acted assertively to expand the supply of credit, it could have stabilized the banking system and limited the damage to the real economy;[91] the Fed's mental model at the time, however, focused on "free reserves," rather than broader measures of money or credit that would have shown the need for more aggressive action. In addition, rescuing the financial system would have required printing money, which, it was feared, would have adverse consequences; generous bailouts of failing insolvent banks would have created incentive problems for the future. But instead, forced liquidation meant bankruptcy not just for companies and farmers, but also for banks.[92] Widespread bank failures encouraged people to withdraw their money from sound banks; this further dried up the credit available to businesses, causing major collateral damage to the economy, and once the financial system began contracting the process became impossible to stop.* As a result, unemployment rose above 20 percent and much of the American population suffered through a terrible decade of lost jobs, poor living standards, and severe dislocation.

Clearly, something had gone badly wrong. The problem was not that a single bank threatened to usurp political power, like the Second Bank of Jackson's day; it was that there was no effective check on the private banks as a group, whose appetite for risk had created a massive boom and a monumental bust.[94] The Federal Reserve alone lacked either the power or the will to rein in the excesses of the financial sector. The cheap money it supplied had only encouraged excessive risk-taking. When the crisis finally arrived, the government was left with the choice between bailing out banks around the country and encouraging a further speculative cycle or letting the system collapse and inviting widespread economic misery.

The only force available to constrain the banking industry was the federal government, setting up another showdown between political reformers and the financial establishment. This time, however, the magnitude and severity of the Great Depression created the opportunity for a sweeping overhaul of the relationship between government and banks. And the Pecora Commission, an investigation initiated by the Senate Banking Committee, uncovered extensive evidence of abusive practices by the banks—from pumping up questionable bonds they were selling to giving insiders stocks at below-market prices[95]—providing the political ammunition necessary to overcome the objections of the financial sector. The result was the most comprehensive attempt in American history to break up concentrated financial power and constrain banks' activities.[96]

Franklin Delano Roosevelt's favorite president was Andrew Jackson.[97] This affinity was not without its ironies. Roosevelt was a man of the Eastern establishment; while Jackson is sometimes referred to as "frontier aristocracy" and had New York allies, he had no affection for the East Coast elite. Still, both men shared an appreciation for the workings of democracy and a fear that unconstrained private interests could undermine both the economy and the political system. In a sense, they were both descendants of Jefferson, and both sought to shift the balance of power between the financial system and society at large. In January 1936, Roosevelt said, "Our enemies of today are the forces of privilege and greed within our own borders.… Jackson sought social justice; Jackson fought for human rights in his many battles to protect the people against autocratic or oligarchic aggression." Roosevelt also stressed that he was opposed to a "small minority of business men and financiers."[98]

Although Roosevelt faced a far more complex economic situation than did Jackson, his goals were similar: to protect society at large from the economic and political power of big banks. And he was not afraid to confront the bankers head-on; as historian Arthur Schlesinger wrote of the Roosevelt administration's first months in power, "No business group was more proud and powerful than the bankers; none was more persuaded of its own rectitude; none more accustomed to respectful consultation by government officials. To be attacked as antisocial was bewildering; to be excluded from the formation of public policy was beyond endurance."[99] The new legislation of the 1930s—primarily the Banking Act of 1933, better known as the Glass-Steagall Act—reduced the riskiness of the financial system, with a particular emphasis on protecting ordinary citizens. The regulatory framework, however, was relatively simple. Commercial banks, which handled deposits made by ordinary households and businesses, needed to be protected from failure; investment banks and brokerages, which traded securities and raised money for companies, did not. The Glass-Steagall Act separated commercial banking from investment banking to prevent commercial banks from being "infected" by the risky activities of investment banks. (One theory at the time—since largely discredited—was that this infection had weakened commercial banks and helped cause the Depression.)[100] As a result, J.P. Morgan was forced to spin off its investment banking operations, which became Morgan Stanley. Commercial banks were protected from panic-induced bank runs by the Federal Deposit Insurance Corporation (FDIC), but had to accept tight federal regulation in return. The governance of the Federal Reserve was also reformed in the 1930s, strengthening the hand of presidential appointees and weakening the relative power of banks.

The system that took form after 1933, in which banks gained government protection in exchange for accepting strict regulation, was the basis for half a century of financial stability—the longest in American history. Investment banks were also subject to new regulation and oversight by the Securities and Exchange Commission (SEC), but this regulatory regime focused primarily on disclosure and fraud prevention—making sure that banks did not abuse their customers, rather than ensuring their health and stability.

Postwar commercial banking became similar to a regulated utility, enjoying moderate profits with little risk and low competition. For example, Regulation Q, a provision of the Banking Act of 1933, allowed the Federal Reserve to set ceilings on savings account interest rates. Since savings accounts were a major source of funds for banks, the effect was to limit competition for customers' deposits while guaranteeing banks a cheap source of funds. Limits on opening branches and on expanding across state lines inhibited competition, as did the prohibition against investment banks taking deposits. As a result, banks offered a narrow range of financial products and made their money from the spread between the low (and capped) interest rate they paid depositors and the higher rate they charged borrowers. This business model was emblematized by the "3–6–3 rule": pay 3 percent, lend at 6 percent, and make it to the golf course by 3 P.M. According to one leading banking textbook, "some banks frowned on employees working in their offices after hours lest outsiders perceive lighted windows as a sign of trouble."[101]

The result was the safest banking system that America has known in its history, despite a substantial increase in leverage. The average equity-asset ratio—the share of lending financed by owners' or shareholders' capital rather than borrowed money—had already fallen from 50 percent in the 1840s to around 20 percent early in the twentieth century as informal cooperation mechanisms developed among banks. But due to the double liability principle (which made bank shareholders potentially liable for up to *twice* the money they had invested), this meant that over 20 percent of bank assets were backed by shareholders' capital—a stunningly high cushion against loss for creditors by modern standards. After the creation of the FDIC backstop in 1933, the equity-asset ratio fell below 10 percent for the first time in history.[102] In other words, banks took on significantly more debt and, in the process, generated higher returns for their shareholders.

Ordinarily, low equity levels (high debt levels) should increase a bank's riskiness by increasing the likelihood that it will not be able to pay off its debts in a crisis. Yet despite the increase in leverage, tighter regulation prevented any serious banking crises. As Figure 1-1 demonstrates, the half-century following the Glass-Steagall Act saw by far the fewest bank failures in American history.[103] But once financial deregulation began in the 1970s, these low equity levels became increasingly dangerous.[104]

Some of the regulations in place during this period may have been excessive. For example, it's not clear that limiting banks to a single state—a long-standing rule in the United States that was reaffirmed in the 1930s—makes them safer (other than by restricting competition, which increases their profits). Even the need for the Glass-Steagall division between investment banks and commercial banks has been questioned,[105] and recent history has shown that pure investment banks could become systemically important (and therefore qualify for government bailouts) on their own. Still, the regulations of the 1930s were consistent with several decades of sustained growth without major financial crises. No one can conclusively prove that these reforms were essential to postwar economic development. But constraints on banking activities helped prevent the development of massive debt-fueled booms ending in spectacular crashes. The extreme boom-bust cycles of the nineteenth and early twentieth centuries faded into memory, while the financial system funneled capital effectively into productive

investments.[106]

Of course, the story does not end there. The society and economy of the United States remain highly dynamic. New businesses and companies appear and old memories fade away. Political settlements hammered out in previous eras start to seem useless or quaint. Eventually the American tendency toward innovation, risk-taking, and profit-making takes over, and new economic elites arise to challenge the political order.

The laws of the 1930s were intended to protect the economy from a concentrated, powerful, lightly regulated financial sector. In the 1970s, they were beginning to look out of step with the modern world. Bright young minds were inventing new types of financial transactions; banks, particularly investment banks, were making more and more money; and the federal government, charmed by the promised miracles of the financial sector, began relaxing the rules. By the 1990s, Jefferson and Jackson, always awkward topics at any discussion of finance and economics, seemed more irrelevant than ever, and Franklin Delano Roosevelt's New Deal was under widespread attack. The financial sector was bigger, more profitable, and more complicated than it had been in decades. Productivity was rising steadily, economic growth was strong, and inflation was stable and low. Just as some political commentators thought the end of the Cold War signaled the end of history, some economic pundits believed that this "Great Moderation" heralded a turning point in economic history. Sophisticated macroeconomic theories and wise policymakers, they suggested, had learned to tame the cycle of booms and busts that had plagued capitalism for centuries.

In fact, the 1990s were a decade of financial and economic crises, but they were taking place far away, on the periphery of the developed world, in what were fashionably known as emerging markets. From Latin America to Southeast Asia to Russia, fast-growing economies were periodically imploding in financial crises that imposed widespread misery on their populations. For the economic gurus in Washington, this was an opportunity to teach the rest of the world why they should become more like the United States. We did not realize they were already more like us than we cared to admit.

* The Tenth Amendment, part of the Bill of Rights, was technically not yet in force, but by the end of 1790 it had been ratified by nine states out of the ten necessary.

* A trust was a form of legal organization used to combine multiple companies into a single business entity.

* Lowering short-term interest rates can also help banks by "steepening the yield curve." Since banks typically borrow for short periods of time and lend for long periods of time, if short-term rates fall while long-term rates remain unchanged, their profit margin—the spread between long- and short-term rates—increases.

* An alternative explanation, advanced by Barry Eichengreen and Peter Temin, is that the Federal Reserve was constrained by its adherence to the international gold standard; expanding the money supply would have caused a severe devaluation of the dollar.[93]

OTHER PEOPLE'S OLIGARCHS

> Financial institutions have priced risks poorly and have been willing to finance an excessively large portion of investment plans of the corporate sector, resulting in high leveraging.
>
> —Korea Letter of Intent to the IMF, December 3, 1997[1]

In the mid-1990s, financial crises in less developed parts of the world were only too common. Mexico had a major meltdown in 1994–1995 and former communist countries such as Russia, the Czech Republic, and Ukraine struggled with severe financial shocks. Then in 1997–1998, what seemed like the mother of all international financial crises swept from Thailand through Southeast Asia to Korea, Brazil, and Russia. The contagion even spread to the United States via Long-Term Capital Management (LTCM), an enormous and terribly named hedge fund, which came to the brink of collapse.

In the United States, economists and policymakers took two main lessons from these crises. The first was that crises could be managed—by pushing other countries to become more like the United States. Through the experiences of 1997–1998, the U.S. Treasury Department and the International Monetary Fund (IMF) developed a game plan for handling financial crises: structural weaknesses such as a failing financial sector had to be dealt with immediately, without waiting for the economy to stabilize. Both directly and through their influence over the IMF, the key architects of U.S. economic policy—Treasury Secretary Robert Rubin, Deputy Treasury Secretary Larry Summers, and Federal Reserve chair Alan Greenspan—pressed crisis-stricken countries to liberalize their financial systems, increase transparency in their political systems, and model the governance of their corporations on the Anglo-American system (with a greater role for mutual funds and other institutional investors). For their pains, the Rubin-Summers-Greenspan trio was featured on the cover of *Time* magazine as the "Committee to Save the World."[2]

The second lesson was that while the U.S. economy was not completely immune to financial panics, any real damage could be contained through a few backroom deals. At the urging of the Federal Reserve, LTCM was essentially bought out and refinanced by a group of private sector banks, preventing a major crisis; a series of interest rate cuts by the Fed even kept the stock market bubble growing for another two years. The mature U.S. financial system, it seemed, could withstand any infection that might spread from the developing world, thanks to its sound financial system and macroeconomic management.

Crises were for countries with immature economies, insufficiently developed financial systems, and weak political systems, which had not yet achieved long-term prosperity and stability—countries like Thailand, Indonesia, and South Korea. These countries had three main characteristics that created the potential for serious instability in the 1990s: high levels of debt, cozy relationships between the government and powerful individuals in the private sector, and dependence on volatile inflows of capital from the rest of the world. Together, these ingredients led to economic disaster. Debt-fueled booms, collapsing bubbles, and panic-stricken financial systems were all reminiscent of the Crash of 1929, but the conventional wisdom was that the United States had put these growing pains behind it, thanks to strong corporate governance, deposit insurance, and robust financial regulation. Emerging market crises were an opportunity for the United States to teach the world how to deal with financial crises. Few people suspected that, despite the many obvious differences between emerging Asian economies and the world's largest economy, some of those lessons would become relevant to the United States only a decade later.

ANATOMY OF EMERGING MARKET CRISES

In the 1950s, South Korea was one of the most economically backward countries in the world, ravaged by war and a half-century of Japanese oppression. No outside observer would have regarded it as a candidate for rapid economic development. By 1997, however, South Korea had arrived—literally, having joined the club of rich countries, the Organization for Economic Cooperation and Development (OECD), in 1996.[3] Korea's leading companies were fast building global reputations in a wide range of technology-intensive sectors, including shipbuilding, computer chips, automobiles, and consumer electronics. Top family-owned business groups ("chaebol") such as Samsung, Daewoo, Hyundai, and LG were increasingly prominent global brands. Korea also benefited from a stable political system, with relatively open elections dating back to 1987.

However, Korea exhibited some of the classic weaknesses that produce emerging market crises. Economic activity was dominated by the giant chaebol, whose weak governance structures did little to constrain the whims of their founders. Hostile takeovers were essentially impossible due to a web of local rules. Institutional shareholders did not effectively monitor or control management.[4] The chaebol were also deeply in debt: Samsung's debt was 3.5 times its equity, Daewoo's was 4.1 times, Hyundai's was 5.6 times, and so on.[5] Leverage (the ratio of debt to equity) in the corporate sector was more than twice that of the United States.[6]

In earlier decades, the chaebol had been kept in check by state-owned banks that had carefully allocated credit, limiting the risk that the system would get out of control.[7] By the 1990s, however, the tables had turned. The chaebol had grown big enough to become a political force of their own.[8] Helped by their newfound political influence, they were in position to borrow on advantageous terms, making it possible to run up debt cheaply. Because Korea was regarded as having a sufficiently mature financial market, symbolized by membership in the OECD, its banks could easily borrow short-term money overseas and make longer-term loans to the corporate sector. Alternatively, the chaebol could borrow directly from foreign banks that were now eager to lend to Korea's booming economy.

The availability of cheap short-term debt led the chaebol to splurge on long-term capital investments. The head of Samsung decided that he needed to add an automotive wing to his already far-flung group—an expensive bet that turned out badly. The founder of Daewoo expanded aggressively into the former Soviet bloc, building manufacturing plants from Eastern Europe to Central Asia, and also placed a big bet on cars. Korean manufacturers, led by Samsung and LG, invested heavily in DRAM chip production capacity, driving down margins. These questionable investments, made possible by cheap borrowing, caused returns on capital to fall—making it harder for the chaebol to repay their ever-increasing debts.

Trouble first appeared in 1996 and early 1997 among smaller chaebol who had made risky bets with borrowed money, attempting to move up to the top tier. Hanbo Group (based on a major steel operation), the number 14 chaebol in 1995,[9] defaulted on its debts in January 1997; Kia, the carmaker that was investing heavily to break into the U.S. market, was also in serious financial trouble.[10] The government stepped in with various rescue packages, even for relatively small chaebol, typically providing subsidies or other forms of assistance so that a relatively healthy company could take over a failing company and limit job losses.[11] The largest firms enjoyed stronger implicit government guarantees—the conventional assumption that the government would not let them go under—which helped protect them from failure.[12] Still, by summer 1997, six of the thirty largest business groups had gone bankrupt.[13]

The Korean model and its high short-term-debt levels seemed sustainable as long as economic prospects looked strong and investors thought that companies could pay them back. But financing long-term investments with short-term foreign debt creates a major vulnerability: if lenders start to worry about getting repaid, they will try to pull out their money (refusing to roll over loans); but because companies put that money in long-term investments, they will not be able to pay it back on demand. In this situation, borrowing in U.S. dollars only increased the vulnerability—fears that a country is in trouble can become self-fulfilling as foreign bankers and bondholders scramble to pull their money out first, triggering the defaults that they were afraid of.

For the first nine months of 1997, the Korean economy grew at an impressive rate of around 6 percent.[14] In July, however, the "Asian financial crisis" broke out in Thailand as a crisis of confidence caused a collapse in the local currency, the baht. Overleveraged companies saw their debts double practically overnight (because their debts were in foreign currencies, the amount they owed doubled when the value of the Thai baht fell by half) and were forced to default, causing mass bankruptcies and layoffs. One month later, the crisis spread to Indonesia, where the currency collapsed and domestic companies failed.

At first investors assumed that Korea was sufficiently developed to withstand the storm, but anxiety was spreading outward from Southeast Asia. On October 23, the Hong Kong stock market declined sharply, rattling investors. Then Standard & Poor's downgraded Korean sovereign and corporate debt, stoking fears that Korea would be the next country to be hit by the crisis.* Financial markets started to think again of Korea as an emerging market subject to high economic volatility, which made its short-term debt levels seem excessive. Foreign banks became reluctant to roll over their loans and new international financing

became hard to obtain. The currency depreciated sharply, falling from 886 won per dollar in July to 1,701 won per dollar in December. Everyone with dollar debts was hit hard, since now it took twice as many won to cover the same dollar debt payments.[15]

The Korean government attempted to stabilize the situation, using its foreign exchange reserves to help state-owned banks pay off their foreign debts and to slow down the depreciation. But it could not stop the downward spiral—as the currency fell, it became harder for companies to repay foreign debts, and as some fell behind on repayments, creditors became more reluctant to roll over the debts of others.[16] The stock market declined sharply and credit collapsed as banks, unable to pay their own foreign debts, reacted by cutting off loans to domestic companies—which made it harder for companies to produce the exports they needed to pay off their debts.[17] The economy declined sharply, leading to layoffs and street protests.

The International Monetary Fund, an intergovernmental organization charged with helping countries in economic distress, did provide financial support subject to some conditions. The IMF emergency lending program put limits on bailouts to the corporate sector, insisted that support to the banking system become transparent and that insolvent banks themselves be taken over, and outlined changes in the governance of chaebol to limit overinvestment. Many of these ideas were strongly supported by Korean reformers working under new president Kim Dae-jung, who wanted to take advantage of chaebol weakness to push through reforms that would make future growth more sustainable—in part by reducing what he saw as the economic and hence political clout of the chaebol.[18]

But the IMF program also contained three striking and controversial dimensions. First, consistent with the view of the U.S. Treasury, it insisted on tightening monetary policy and, despite the strength of the government's balance sheet, did not condone an increase in government spending to offset the contraction in the private sector.[19] As a result, Korea was unable to cushion its economic downturn with the type of stimulus package and low interest rates deployed by the United States and most developed countries in 2008–2009.[20]

Second, in the debt renegotiations with foreign lenders, which involved the U.S. Treasury closely,[21] there was no write-down of the amount owed by Korean banks; although the United States did help force creditors to roll over their loans, the amount they were owed did not change. So while Korean companies were left to struggle, foreign banks and bondholders were effectively bailed out of their poor lending decisions—giving them no incentive to avoid the same mistakes in the future.[22]

Third, the IMF insisted that Korea needed to become *more* open to foreign capital, quickly. Paragraph 31 of the Letter of Intent between Korea and the IMF reads as follows:

> To increase competition and efficiency in the financial system, the schedule for allowing foreign entry into the domestic financial sector will be accelerated. Foreign financial institutions will be allowed to participate in mergers and acquisitions of domestic financial institutions in a friendly manner and on equal principles. By mid-1998, foreign financial institutions will be allowed to establish bank subsidiaries and brokerage houses. Effective immediately foreign banks will be allowed to purchase equity in domestic banks without restriction, provided that the acquisitions contribute to the efficiency and soundness of the banking sector.[23]

The premise was that the crisis had not occurred because Korea was too exposed to volatile flows of short-term foreign capital, but because it was not open enough to foreign direct investment, including in the financial sector. To many observers, it looked like the IMF and the United States were taking advantage of the crisis to push forward their program of global financial liberalization.[24]

While every crisis is unique, Korea was in many ways typical of the experiences of emerging markets in the 1990s. Large, well-connected companies expanded rapidly by taking on large amounts of cheap debt, unconstrained by the forces that should prevent irresponsible corporate behavior in a capitalist economy; outside shareholders had little influence over powerful founders, and creditors lent money freely, assuming that the leading chaebol were too important for the government to let them go bankrupt.[25] Even though state-owned banks nominally controlled the flow of capital, tight relationships between the private sector and the government meant that the chaebol felt they had little to fear. Political factors played an important role in the economic crisis.

This central role of politics is common to many emerging market crises. Political connections were even more crucial in Indonesia, where the late President Suharto could never be mistaken for Thomas Jefferson. Under no possible interpretation was Suharto interested in protecting citizens against the power of the government. Instead, his goals were some combination of maintaining order, improving the economic welfare of ordinary people, and enriching his own inner circle.

Suharto adopted neither a communist-style planned economy nor an "anything goes" free market system. Instead, he cultivated a small group of private businesspeople whose family businesses became the backbone of the economy. Aided by the president and his family, who opened doors for their friends (and shut them for their competitors), these entrepreneurs built

factories, developed cities, and learned how to export raw materials, agricultural products, and simple manufactured items to the rest of the world. As in many other low-income countries in the past half-century, economic development was dominated by a small economic elite defined by their personal ties to the ruling family, which traded favors for both political support and cold, hard cash—a pattern known as "crony capitalism."[26] For example, Indofood became one of the largest conglomerates in the country, largely because of a longtime personal friendship between its founder, Liem Sioe Liong, and Suharto.[27] Suharto's wife, Siti Hartinah Suharto, known as Madame Tien, was involved in so many business deals that she was referred to by critics as "Madame Tien Percent" for her alleged fees.[28] Suharto's children also cut themselves into many major deals; his daughter was involved in the largest taxi company, one son tried to build cars, and another son was a financial entrepreneur.[29]

For a long time, the system worked reasonably well. Annual income per capita grew from $1,235 in 1970, just after Suharto came to power, to just over $4,545 by 1997.[30] Indonesia was still a poor country with pervasive poverty, but thirty years of economic growth had created higher standards of living for millions of people. The country was regarded as a development success story by the World Bank and by foreign investors, who supplied much of the capital needed to build factories, roads, and apartment buildings. Everyone knew that the flow of capital was controlled by Suharto's family and friends, but this was actually attractive to investors, who quite reasonably thought it safer to lend money to people with strong political connections. The increasing availability of foreign capital fueled economic growth.

But easy money also fueled overinvestment and increasing risktaking, especially by well-connected businesspeople who assumed they would be bailed out by their powerful friends if things turned out badly. And over time, success in business became less a question of innovation and sound management than of using political connections to obtain government favors and subsidies. The result was an economic boom that could be sustained only by ever-increasing amounts of foreign debt, which came crashing down in 1997.

Russia provided a different example of the dangers created by a well-connected economic elite with easy access to foreign capital. With the collapse of communism after 1991, many former Soviet republics attempted to build capitalist economies with independent private sectors. In Russia, with its vast reserves of oil and gas, privatization of state enterprises provided a direct route to creating the major companies that would be the foundation of the economy. The reformers in the government of President Boris Yeltsin initially planned to create companies with a large number of relatively small shareholders. But in 1995, with Yeltsin facing a difficult reelection campaign the next year, they allowed a small group of powerful businessmen to buy large stakes in major state enterprises cheaply; in return, the businessmen provided crucial financial and media support to Yeltsin during the campaign. This was the creation of the Russian oligarchs, who dominated the economy in the 1990s.[31]

The new power of the oligarchs, however, did not translate into strong economic growth or fiscal stability for the government, whose tax revenues depended heavily on the volatile price of oil. Needing to keep social spending at a reasonable level to avoid widespread protests, the IMF (and the United States) encouraged the Russian government to open up the country to capital so that foreigners could lend enough money to bridge the government into more prosperous times—the idea being that Russia could pay back those loans with future economic growth.[32] Private capital could also help restructure the oil and gas industry, develop new fields, and fund other productive investment projects that had been neglected under communism—even if the entire enterprise had a pungent whiff of corruption.

However, Russia's fragile economy was vulnerable to the financial crisis that began in Asia in 1997. The resulting slowdown in global economic growth caused drops in the prices of the commodities that Russia exported, notably oil, hurting both company profits and government tax revenues. By mid-1998, both the government and the private sector were in serious trouble because they had large short-term debts to global banks and foreign investors—and those debts were magnified by the falling value of the ruble. Even an emergency IMF loan in July 1998 could not bail the government out of its problems, and in August Russia was forced to default on its foreign debts, causing massive capital flight out of the country.[33]

NOT ENOUGH LIFEBOATS

Financial crises, at least in emerging markets, have political roots. Although severe crises are generally preceded by a large buildup of debt, that appetite for debt is the product of political factors, most often including close relationships between the economic and political elites.

The downward spiral that occurred in Korea, Indonesia, Russia, and other countries hit by the 1997–1998 crisis was remarkably steep. When foreign credit disappears, economic paralysis ensues; the government is forced to use its own foreign currency reserves to pay for imports, service debt, and cover losses in the private sector. If the country cannot right itself before defaulting on its own government debts, it risks becoming an economic pariah.

As the currency collapses, companies default on their debts, and unemployment rises sharply, the reality on the ground becomes nasty. Leading businesspeople—often selected for their personal relationships or political skills rather than their management ability—focus on saving their most prized possessions. Facing shorter time horizons, executives care less about the long-term value of their firms and more about their friends and themselves. As George Akerlof and Paul Romer wrote in their classic paper on "looting," businesspeople will profit from bankrupting their own firms when "poor accounting, lax regulation, or low penalties for abuse give owners an incentive to pay themselves more than their firms are worth and then default on their debt obligations."[34]

In Russia, as in most emerging market crises, there was a sharp increase in "tunneling"—borderline illegal ways for managers and controlling shareholders to transfer wealth from their businesses to their personal accounts.[35] Boris Fyodorov, a former Russian minister of finance who struggled against corruption and the abuse of authority, argued that confusion only helps the powerful;[36] when there are complicated government bailout schemes, multiple exchange rates, or high inflation, it becomes difficult to monitor the real market prices of assets and protect the value of firms.[37] In the extreme confusion caused by a crisis, insiders can take the money (or other valuables) and run, leaving banks, industrial firms, and other entities to collapse. Alternatively, confusion means that government officials have extraordinary discretion to save firms or let them fail. Describing an earlier financial crisis, Carlos Diaz-Alejandro wrote,

> [T]he ad hoc actions undertaken during 1982–83 in Chile to handle the domestic and external financial crisis carry with them an enormous potential for arbitrary wealth redistribution.… Faith in orderly judicial proceedings to clear up debts and claims on assets appeared to be quite low; stories abounded of debtors fleeing the country, and of petty and grand financial chicanery going unpunished.[38]

From a macroeconomic perspective, the government needs to restore the confidence of foreign investors. Large government deficits (Russia) require cuts in government spending and higher taxes; large private sector debts (Korea and Indonesia) need to be rescheduled; and to attract capital, interest rates need to be higher, even though this hurts the local economy.

But responding to crises also has a political dimension. The IMF is ready to lend money, but only if it (along with its backers among the major industrial countries) believes that the government has sufficient political will to sustain the policies necessary to stabilize the situation; in the case of Indonesia, for example, this involved cutting back on the cozy relationships with economic elites that helped produce the crisis.[39] This means less use of national reserves to cover the local private sector's debts, less bailout money for the banking system, and fewer subsidies all around. Essentially, the government needs to choose whom to save; it has to squeeze at least some of the oligarchs. Of course, this is rarely the strategy of choice among emerging market rulers, whose reflex is to protect their old friends when the going gets rough—it can be tough to find new supporters in the middle of a crisis—even coming up with innovative forms of subsidies, such as guaranteeing the debts of private companies. In some instances, rulers prefer, at least in the short term, to inflict pain on the working class through layoffs, reduced government services, and higher taxes, on the assumption that big private businesses produced the original boom and can also drive the recovery.

Eventually, however, at least some within the elite have to lose out, both because there aren't enough foreign currency reserves to cover everyone's debts and because external lenders (first among them the IMF) demand some sign that the excessive risk-taking that produced the crisis is being punished. In both Thailand and Indonesia in 1997, the real fight was over which powerful families would lose their banks. In Thailand, the issue was handled relatively smoothly; more than fifty Thai "finance houses" (lightly regulated financial intermediaries) were shut down and some of the country's largest banks were taken over by the government. In Indonesia, however, the question was whether the parliamentary government would close the banking operations belonging to one of President Suharto's sons. In the struggle that ensued, the son's bank first lost its license to operate, but then appeared to have obtained another license with the suspected aid of the presidential palace; in the end, local officials did not have sufficient political will or power to stand up to the ruling family, undermining IMF (and U.S.) support and deepening the economic crisis.[40] In Korea, the confrontation was between the government and the largest chaebol,

some of which had quite blatantly broken the law. After a series of showdowns—in which Daewoo threatened to default and political forces rallied to its assistance—the government won, and the hugely powerful Daewoo group went through bankruptcy and restructuring.

It is unheard of that all the oligarchs lose out, since the government can easily claim that they are essential to the domestic economy; some typically become even more powerful by absorbing their rivals, as happened in Korea, where Hyundai acquired the failing Kia. As the oligarchs in Yeltsin's Russia found out in 1998, it's a game of musical chairs; the post-crash government has enough foreign exchange reserves to help some big companies pay their debts, but not all of them. Usually the biggest of the big—the top chaebol, Suharto's close business allies (under the protection of Bacharuddin Jusuf Habibie, who succeeded Suharto as president), and the large Russian natural resource companies (such as Gazprom)—survive and prosper thanks to generous bailouts and other forms of government support. It's their smaller competitors who are cut adrift, while ordinary people suffer through government "austerity measures." Of course, the "dispossessed" oligarchs fight back, calling in political favors or even trying subversion—including calling up their contacts in the American foreign policy establishment, as the Ukrainians did with some success in the late 1990s.[41] But the aftermath of an emerging market crisis typically leads to a shakeout of the oligarchy, with political power concentrated in a smaller number of hands.

However, another common feature of emerging market crises is that they don't last forever. Even while outside observers are still despairing over corporate governance, macroeconomic management, and crony capitalism, growth picks up again. In 1999, the Korean economy grew by 11.1 percent; the Russian recovery took slightly longer, with growth of 4.5 percent in 1999 and 11 percent in 2000; and while growth took longest to resume in Indonesia, by 2000 its economy was expanding at close to 4 percent per year.[42] A lower exchange rate boosts exports, widespread unemployment reduces the cost of labor, and companies with rescheduled debts or new companies with clean books can take advantage of both higher sales and lower costs. Surviving businesses can use their increased market shares and reaffirmed political connections to grow bigger and stronger. The oligarchs who run them can become even wealthier; Carlos Slim bought up companies on the cheap after the 1982 crisis in Mexico and used the boom-bust cycle of the early 1990s (and his strong political connections) to consolidate his dominant position in telecommunications—becoming one of the world's richest men in the process.[43]

Growth can come back without any real fundamental reforms. Foreign lenders learn exactly the wrong lessons from a crisis: they learn that when push comes to shove, the IMF will protect them against the consequences of their bad investments; and they learn that it's always best to invest in the firms with the most political power (and hence the most assurance of being bailed out in a crisis), perpetuating the pattern of crony capitalism. As a result, foreign capital flows back, and emerging markets can repeat the boom-bust-bailout cycle for a long time, perhaps indefinitely.

But long-term economic growth is unlikely to result. Although oligarchies may be consistent with episodes of growth, they are not good at supporting the development of new entrepreneurs and the commercialization of new technologies.[44] In fact, entrenched economic elites may have an interest in limiting competition from new ideas and new people. Political elites, dependent on those economic elites for support, are unlikely to adopt policies to increase competition. Without a business environment that promotes innovation and competition from new entrants—like the one enjoyed by the United States early in the nineteenth century—periodic episodes of debt-fueled expansion do not add up to sustained economic growth.

Fundamental reform requires more than rearranging the seats on the government lifeboat; it requires weakening the economic and political power of the oligarchs and creating a healthier, more competitive economic system. This is only possible for a government with an independent base of support and legitimacy strong enough for it to challenge the economic elites. These are tough conditions to achieve, but not impossible ones, as the Korean case shows.

Korea had the advantage of a serious reformer, Kim Dae-jung, winning the presidency a month after the crisis hit.[45] Kim had fought for years against the previous regime and its backers and was deeply skeptical of the chaebol and the claim that they needed special treatment. He had numerous allies, including the prominent People's Solidarity for Participatory Democracy, which lobbied hard for corporate governance reform as a way to constrain the chaebol, strengthen the economy, and protect democracy.[46] Big companies such as SK Telecom and Samsung Electronics were forced to become more transparent to protect minority shareholders against looting. The government also pushed through reforms limiting the power of the chaebol: they were no longer allowed to cross-guarantee debts within groups, investments across companies within a chaebol were curtailed, the number of affiliated companies within a chaebol was reduced, large companies were required to have outside directors, financial disclosure requirements were strengthened, chaebol control over the nonbank financial sector was restricted, and there was a push to reduce debt levels.[47]

Although the reforms did not solve all of the problems presented by economic concentration, they did lead to a solid economic recovery. The rapid expansion of 1999 and 2000 was followed by annual growth of 4–5 percent in the early 2000s—a respectable rate for a country as developed as Korea, though slower than during the pre-1997 period. There is an active debate in Korea over whether the post-crisis corporate and political reforms went far enough; the largest chaebol, including Samsung, LG, SK, and Hyundai, still dominate the economic landscape. But the reforms were a step in the right direction,

because they addressed the core problem that led to the crisis—concentration of economic power in an elite with the ability to influence the political system.

Ultimately, ending the cycle of debt-fueled bubbles and wrenching crises takes more than an IMF bailout package and a new minister of finance with a Ph.D. from an American university.[48] Since emerging market crises are the result of political conditions, sustained growth requires an end to the close relationships between economic and political elites that distort the competitive environment and encourage the misallocation of capital. Making this transition successfully is one of the central challenges for all emerging market economies.

NO WORRIES

Few people, if any, thought that these crises had anything to teach the United States, the world's richest economy and flagship democracy. The differences between Indonesia or Korea and the United States are obvious: income level, financial system, political track record, and so on. Our most ingrained beliefs run directly counter to the idea that a rich, privileged oligarchy could use government relationships to enrich itself in the good times and protect itself in the bad times. Our economic system is founded on the notion of fair competition in a market free from government influence. Our society cherishes few things more than the idea that all Americans have an equal opportunity to make money or participate in government. There is no construct more important in American political discourse than the "middle class."

The United States was not untouched by the emerging markets crisis of 1997–1998. In 1998, the most prestigious hedge fund in the world was arguably Long-Term Capital Management, founded only four years before in Greenwich, Connecticut, by a legendary trader, two Nobel Prize–winning economists, and a former vice chair of the Federal Reserve, among others.[49] When the crisis broke out, LTCM had about $4 billion in capital (money contributed by investors), which it had leveraged up with over $130 billion in borrowed money.[50] It bet that money not on ordinary stocks or bonds, but on complex arbitrage trades (betting that the difference between the prices of two similar assets would vanish) and directional trades (for example, betting that volatility in a given market would decrease).

However, LTCM's models were based on data gathered under ordinary market conditions. When the financial crisis spread and various markets seized up, it began losing money on many of its major trades, and its capital fell to less than $1 billion. But the real problem was that with LTCM on the verge of becoming insolvent, the banks and hedge funds that had lent it money (either directly or through derivatives transactions) were at risk of losing billions of dollars of their own. Fearing the damage an LTCM failure could do to the financial system as a whole, the Federal Reserve Bank of New York brought together representatives from the largest New York banks and pressured them to find a solution. In September 1998, the banks put in $3.6 billion of new money in exchange for a 90 percent ownership stake in the fund, largely wiping out the existing partners; with the new money, LTCM was able to ride out the storm without causing any collateral damage.

LTCM proved that in the new, globalized world, contagion from faraway emerging markets could spread to the United States. However, it also seemed to prove that any damage could be contained through effective intervention and sound macroeconomic management, without requiring taxpayer money or slowing down the real economy. As the long boom of the 1990s continued and the stock market continued to go up, LTCM soon faded into memory.

U.S. policymakers did draw a number of important lessons from the emerging market crises, outlined by Treasury Secretary Larry Summers in a major lecture at the 2000 conference of the American Economics Association.[51] Financial crises were the result of fundamental policy weaknesses: "Bank runs or their international analogues are not driven by sunspots: their likelihood is driven and determined by the extent of fundamental weaknesses." It was more important to look at the soundness of the financial system than to simply count the total amount of debt: "When well-capitalized and supervised banks, effective corporate governance and bankruptcy codes, and credible means of contract enforcement, along with other elements of a strong financial system, are present, significant amounts of debt will be sustainable. In their absence, even very small amounts of debt can be problematic." Companies should not be allowed to expect government support in a time of crisis: "It is certain that a healthy financial system cannot be built on the expectation of bailouts." And in a time of crisis, it was critical to take rapid action to clean up failing banks: "Prompt action needs to be taken to maintain financial stability, by moving quickly to support healthy institutions and by intervening in unhealthy institutions." The best advice Summers offered was a principle famously associated with Mexican president Ernesto Zedillo during a crisis earlier in the decade: "markets overreact, so policy needs to overreact as well."

These were all valid conclusions. In summary, they meant that emerging market countries should become more like the United States, with our strong legal institutions, transparent accounting, elaborate bank regulations, and independent political system—or, more accurately, they should become more like the conventional image that we held of our own country.

The idea that a major financial crisis of the type that ravaged emerging markets in the 1990s could originate in the United States was too preposterous to even be conceived of. Two of the crucial ingredients—tight connections between economic and political elites and dependence on fickle short-term flows of foreign capital—seemed completely out of the picture.[52] Despite rising debt due to growing trade imbalances, Summers's argument implied that our superior financial system made high debt levels sustainable. More fundamentally, political economy—the study of interactions between the political and economic systems—was only appropriate for developing and emerging market countries. In countries that had already "emerged," like the United States, economic questions could be studied without reference to politics. Instead, economic and financial policy presented only technocratic questions, which Summers compared to regulation of air travel:

> The jet airplane made air travel more comfortable, more efficient, and more safe, though the accidents were more spectacular and for a time more numerous after the jet was invented. In the same way, modern global financial markets

carry with them enormous potential for benefit, even if some of the accidents are that much more spectacular. As the right public policy response to the jet was longer runways, better air-traffic control, and better training for pilots, and not the discouragement of rapid travel, so the right public policy response to financial innovation is to assure a safe framework so that the benefits can be realized, not to stifle the change.

———

But in September-October 2008, when Lehman Brothers collapsed and panic seized the U.S. economy, money flooded out of the private financial system in what looked like a classic emerging market crisis.* In retrospect, it was clear that the run-up in housing prices of the 2000s was a bubble fueled by over-optimism and excess debt worthy of any emerging market. The diagnosis of the 1997 Korean Letter of Intent seemed to apply perfectly to 2008 America (substituting "household" for "corporate"): "Financial institutions have priced risks poorly and have been willing to finance an excessively large portion of investment plans of the corporate sector, resulting in high leveraging. At the same time, the dramatic decline in stock prices has cut the value of banks' equity and further reduced their net worth."[53] And when the federal government began rescuing major banks presided over by ultra-wealthy executives—while letting smaller banks fail by the dozens—it began to seem as if our government was bailing out its own, uniquely American oligarchy.

In similar situations in the 1990s, the United States had urged emerging market countries to deal with the basic economic and political factors that had created devastating crises. This advice was often perceived as arrogant (especially when the United States also insisted that crisis-stricken countries open themselves up further to American banks), but the basic logic was sound: when an existing economic elite has led a country into a deep crisis, it is time for change. And the crisis itself presents a unique, but short-lived, opportunity for change.

As in Korea a decade before, a new president came to power in the United States in the midst of the crisis. And just like Kim Dae-jung in Korea, Barack Obama had campaigned as the candidate of change. Yet far from applying the advice it had so liberally dispensed to others, the U.S. government instead organized generous financial support for its existing economic elite, leaving the captains of the financial sector in place.

What had happened?

* Standard & Poor's and other credit rating agencies rate bonds issued by governments and companies. The ratings are supposed to reflect the likelihood that the issuer will pay off its debts. A rating downgrade indicates that the agency is losing confidence in the issuer.

* There was one huge difference, which was that money did not leave the country; instead, it left the private sector for the safety of U.S. Treasury obligations. But the effect on the private sector financial system was the same.

1980–

In this present crisis, government is not the solution to our problem; government is the problem.

—Ronald Reagan, inaugural address, January 20, 1981[1]

On December 9, 1985, the cover of *Business Week* featured John Gutfreund, the CEO of Salomon Brothers and "The King of Wall Street." "Merrill Lynch remains the best-known Wall Street house and Goldman Sachs the best-managed, but Salomon Bros. is the firm most feared by its competitors," wrote Anthony Bianco. "It is the prototype of the thoroughly modern investment bank—the not-so-benevolent King of the Street."[2]

Salomon was the epitome of the new breed of Wall Street investment bank, built around a swashbuckling, risk-taking bond trading operation powered by "quants" recruited from academic research institutions and filled with "financial engineers" designing new products. Its strategy was to take large risks on its own account rather than simply taking fees for providing advice or executing trades. As Bianco put it, "What sets Salomon apart is the sheer scale on which it oper-ates in the markets, reflecting an appetite for risk unrivaled among financial middlemen." Four years later, *Liar's Poker,* Michael Lewis's memoir of his years at Salomon, would cement its status as the paradigmatic bank of the 1980s, the same decade that produced the original Oliver Stone *Wall Street* movie, with Gordon Gekko's famous "Greed is good" speech.

Looking back, however, Salomon seems so … small. When the *Business Week* story was written, it had $68 billion in assets and $2.8 billion in shareholders' equity. It expected to earn $1.1 billion in operating profits for all of 1985. The next year, Gutfreund earned $3.2 million.[3] At the time, those numbers seemed extravagant. Today? Not so much.

If the financial crisis of 2007–2009 produced a king of Wall Street, it would most likely be Jamie Dimon, CEO of JPMorgan Chase and the "Last Man Standing," according to the title of a recent book.[4] (Lloyd Blankfein of Goldman Sachs would be the other contender.) Compared to other megabanks, JPMorgan was less exposed to toxic securities and came through the credit crisis in better shape. In addition, it capitalized on the problems of other banks to snap up Bear Stearns and Washington Mutual, gaining strength in both investment banking and retail banking. And it took advantage of its weakened competitors to grab market share across the board, taking the top spot in investment banking revenues in the first half of 2009.[5] At his company's annual meeting in May 2009, Dimon could justifiably claim, "This might have been our finest year ever."[6] In addition, his status as a longtime Democratic donor with strong political connections, as well as the Obama administration's need to work with someone on Wall Street, gave him increased influence in Washington. Dimon, *The New York Times* wrote in July 2009, "has emerged as President Obama's favorite banker, and in turn, the envy of his Wall Street rivals."[7]

At the time, JPMorgan Chase had over $2 trillion in assets,[8] not counting positions not recorded on its balance sheet, such as derivatives exposures; it had $155 billion in balance sheet equity; and it earned $4.1 billion in operating profits in the second quarter alone. By comparison, the 1985 Salomon Brothers, even after converting to 2009 dollars to account for inflation, only had $122 billion in assets, $5 billion in equity, and $2 billion in operating profits for an entire year.[9] (Goldman Sachs, as a pure investment bank, offered perhaps a more accurate comparison to Salomon; in the second quarter of 2009, it had $890 billion in assets, $63 billion in equity, and $5 billion in operating profits.)[10]

Although Dimon voluntarily took no cash bonus for 2008, his total compensation including stock awards was still $19.7 million, more than three times Gutfreund's inflation-adjusted earnings of $5.8 million.[11] And this was in a bad year for Wall Street CEOs; in 2007, Dimon earned $34 million, Blankfein $54 million, John Thain of Merrill Lynch $84 million, and John Mack of Morgan Stanley $41 million.[12]

Something changed during the last quarter-century. One factor was a wave of mergers that created fewer and fewer, but larger and larger, financial institutions. JPMorgan Chase was the product of the mergers of Chemical Bank, Manufacturers Hanover, Chase Manhattan, J.P. Morgan, Bank One, and First Chicago—all since 1991—even before the bargain-basement acquisitions of Bear Stearns and Washington Mutual in 2008. (Salomon itself was acquired by Travelers, which then merged with Citicorp into Citigroup.)

In addition, the financial sector itself simply got bigger and bigger. When John Gutfreund became CEO of Salomon in 1978, all commercial banks together held $1.2 trillion of assets, equivalent to 53 percent of U.S. GDP. By the end of 2007, the commercial banking sector had grown to $11.8 trillion in assets, or 84 percent of U.S. GDP. But that was only a small part of the story. Securities broker-dealers (investment banks), including Salomon, grew from $33 billion in assets, or 1.4 percent of GDP, to $3.1 trillion in assets, or 22 percent of GDP. Asset-backed securities such as collateralized debt obligations (CDOs), which hardly existed in 1978, accounted for another $4.5 trillion in assets in 2007, or 32 percent of GDP.* All told, the debt held by the financial sector grew from $2.9 trillion, or 125 percent of GDP, in 1978 to over $36 trillion, or 259 percent of GDP, in 2007.[13]

Some of this growth was due to an increase in borrowing by the nonfinancial sector—the "real economy." However, the expansion of the financial sector vastly outpaced growth in households and nonfinancial companies. Instead, most of the growth in the financial sector was due to the increasing "financialization" of the economy—the transformation of one dollar of lending to the real economy into many dollars of financial transactions. In 1978, the financial sector borrowed $13 in the credit markets for every $100 borrowed by the real economy; by 2007, that had grown to $51.[14] In other words, for the same amount of borrowing by households and nonfinancial companies, the amount of borrowing by financial institutions quadrupled.

Even these numbers do not include the derivatives positions that financial institutions were building up at the same time, because derivatives—bets on the value of other assets, such as stocks or currencies—are not conventionally accounted for on bank balance sheets. Worldwide, over-the-counter derivatives, which essentially did not exist in 1978, grew to over $33 trillion in market value—over twice U.S. GDP—by the end of 2008.[15] A large portion of these derivatives was held by U.S. financial institutions, which were among the world leaders in the business. No matter how you measure it, the size and economic influence of America's financial sector grew enormously over the past thirty years; the Salomon Brothers of 1985 would be trivial today.

As the financial sector amassed more and more assets, it became a bigger part of the national economy. Between 1978 and 2007, the financial sector grew from 3.5 percent to 5.9 percent of the economy (measured by contribution to GDP).[16] Its share of corporate profits climbed even faster, as shown in Figure 3-1. From the 1930s until around 1980, financial sector profits grew at roughly the same rate as profits in the nonfinancial sector. But from 1980 until 2005, financial sector profits grew by 800 percent, adjusted for inflation, while nonfinancial sector profits grew by only 250 percent. Financial sector profits plummeted at the peak of the financial crisis, but quickly rebounded; by the third quarter of 2009, financial sector profits were over six times their 1980 level, while nonfinancial sector profits were little more than double those of 1980.[17]

Not surprisingly, bankers' salaries and bonuses also shot upward. In 1978, average per-person compensation in the banking sector was $13,163 (in 1978 dollars)—essentially the same as in the private sector overall, which averaged $13,142. From 1955 through 1982, the average banker's compensation fluctuated between 100 percent and 110 percent of average private sector pay. Richard Fisher, chairman of Morgan Stanley in the 1990s, recalled that when he left Harvard Business School in the early 1960s, "investment banking was about the worst-paying job available to us. I started at Morgan Stanley at $5,800 a year. It was the lowest offer I had … I'm sure my classmates who went to Procter & Gamble started at $9,000 a year."[18] Then banking pay took off, until by 2007, the average banker was making over twice as much as the average private sector employee.[19]

This trend was driven by stupendous growth at the top end of the income distribution. In *Liar's Poker,* $800,000 counted as a big bonus for an experienced trader.[20] In 1990, Salomon Brothers paid its top traders then shocking cash bonuses of more than $10 million.[21] In 2009, it emerged that a single executive at Citigroup—head of a commodities trading group that was loosely descended from Salomon—was due a $100 million bonus.[22] And the real money was in hedge funds; in 2007, five fund managers earned at least $1 billion each for themselves, led by John Paulson, who made $3.7 billion successfully betting against the housing market and the mortgage-backed securities built on top of it.[23]

Bigger, more profitable, and richer—the financial sector grew in every way imaginable during the last three decades. Most important, it became more powerful.

BORING BANKING

This is not what a casual observer would have expected in the 1970s, a time when the financial sector composed just over 3 percent of U.S. GDP and paid its workers little more than the private sector overall. For the entire postwar period, finance had generally been what the authors of the Depression-era banking regulations intended it to be—safe and boring. As described in chapter 1, the regulatory framework created in the 1930s prescribed a strict separation between commercial and investment banks. Commercial banks had an explicit government guarantee in the form of federal deposit insurance, but paid for it with tight federal regulation. Boxed in by rules limiting the businesses they could engage in, the states they could enter, and the interest rates they could pay (but also protected from competition by those same rules), commercial banking became the stereotype of a conservative, low-risk profession.

Investment banking, though riskier, was a far cry from the trading floor of *Liar's Poker,* where traders routinely risked hundreds of millions of dollars and ate guacamole out of five-gallon drums.[24] Like commercial banking, investment banking had taken on the features of a cozy cartel. For example, commissions on stock trading had been fixed (since 1792) by the New York Stock Exchange, preventing price competition. Securities firms earned most of their revenues from the traditional businesses of underwriting stocks and bonds (finding buyers for new securities being issued by corporations), providing brokerage services for institutional clients and an increasingly affluent public, and advising companies on mergers and acquisitions. These businesses were built around long-term client relationships, where reputation mattered. Leading banks such as Morgan Stanley cultivated an image as genteel, "white shoe" firms that emphasized client service rather than making a buck. As Nicholas Brady, treasury secretary in the administration of George H. W. Bush and a former investment banker, said in 2009, "When I came to Wall Street in 1954, it was a profession, one that financed the building of this country's industrial capacity and infrastructure."[25]

At the time, nonfinancial corporations had relatively simple financial needs, at least compared to the plethora of products and services available today: they raised short-term money by taking out bank loans, they raised long-term money by issuing bonds, and they raised capital by issuing stock. The loans were extended and held by commercial banks; the bonds and stocks were placed by investment banks with investors for a small slice of the proceeds. Since investment banks were not making loans directly, holding large chunks of corporate debt or equity, or trading large volumes of securities on their own account, there was little need for massive investment banks; from 1946 through 1981, total financial assets of all securities broker-dealers remained under 2 percent of U.S. GDP.[26]

"Boring banking" was reflected in the nature of the work done in the financial industry, which would be largely unrecognizable to people accustomed to today's era of quantitative sophistication and perpetual innovation. Thomas Philippon and Ariell Reshef have analyzed the task complexity of the jobs done by employees in financial services firms over the last century (Figure 3-2) and found that math aptitude and decision-making were less important between 1940 and 1970 than either earlier or later in the century. By contrast, finger dexterity and routine administrative tasks were relatively more important during this period than in the earlier or later periods.[27]

This does not mean that bankers somehow became noncompetitive and lost the urge to make money after the Depression. There were plenty of attempts to skirt existing banking regulations. Large bank holding companies evaded restrictions on interstate banking by buying separate subsidiary banks in multiple states; thrifts—savings banks and savings and loan associations founded to serve households—competed for deposits by offering interest rates above what commercial banks could pay. But during this period, the federal government took active steps to close regulatory loopholes and maintain the basic framework created in the 1930s. The Bank Holding Company Act of 1956 increased regulation of bank holding companies and limited their ability to buy banks in multiple states. In 1966, Congress gave the Federal Reserve authority to regulate deposit rates paid by thrifts. Congress even expanded the regulatory framework to include stronger consumer protection measures, such as the Truth in Lending Act of 1968 and the Fair Credit Reporting Act of 1970. Not only was the government making sure that banks were safe and sound, it was trying to make sure that banks did not abuse their customers.[28]

During most of this period, the American economy flourished. From 1947 to 1973, real GDP (adjusted for inflation) grew at an average annual growth rate of 4.0 percent,[29] and American corporations grew, prospered, and expanded throughout the world. This was a period of major technological innovation in multiple capital-intensive industries, as the middle class bought cars and household appliances, the government spent heavily on an increasingly sophisticated defense industry, and the revolution in computer technology began with the development of mainframes and minicomputers. It also saw the emergence of the modern venture capital industry, which has played a crucial role in the funding of technological innovation. There were many reasons for the success of the postwar economy, but it is clear that "boring banking" did not constrain financing of innovation and development. Instead, it facilitated a phase of tremendous growth in economic output and prosperity.

CHANGING BANKING

Beginning in the 1970s and accelerating through the 1980s, the financial services industry broke free from the constraints of the Depression-era bargain. While there were banking executives who hoped for wholesale deregulation, there was no concerted plan by the financial sector to overthrow its regulatory constraints. Instead, like many historical phenomena, this development emerged from a confluence of factors: exogenous events, such as the high inflation of the 1970s; the emergence of academic finance; and the broader deregulatory trend begun in the administration of Jimmy Carter but transformed into a crusade by Ronald Reagan. The eventual result was an out-of-balance financial system that still enjoyed the backing of the federal government—what president would allow the financial system to collapse on his watch?—without the regulatory oversight necessary to prevent excessive risk-taking.

Like many major trends, this one was not entirely visible to its participants at the outset. Throughout American history, regulatory change has been more about settling disputes between segments of the business community than about sweeping social transformations, and the beginnings of financial deregulation were no different.

Fixed commissions for stock trading were one of the first dominoes to fall. As David Komansky, later CEO of Merrill Lynch, recalled, "There was no discounting, no negotiating. Fixed prices meant fixed prices for the entire Street; we couldn't give you a discount even if we wanted to. It was the greatest thing in the world."[30] Most Wall Street brokerage firms were happy to profit from this cartel. But not everyone saw things this way. Large institutional investors such as mutual funds and pension funds, which had grown in importance as increasingly affluent Americans amassed savings and large corporations set up pension plans for their employees, wanted lower prices for their large orders. Donald Regan, CEO of Merrill Lynch in the early 1970s, also wanted an end to fixed commissions. Merrill, as the largest broker on Wall Street, stood to gain the most from competition, and Regan already had a vision of his company as a large, diversified financial services firm.[31] William Salomon, then head of Salomon Brothers, also supported an end to fixed commissions.[32]

Called upon to adjudicate this dispute in the early 1970s, the Securities and Exchange Commission obliged, ordering the elimination of fixed commissions in the New York Stock Exchange (NYSE).[33] The NYSE complied on May 1, 1975, which had ripple effects through-out the securities industry. Competition over brokerage commissions meant that institutional investors could make large trades much more cheaply, leading to an increase in trading volume. After enjoying comfortable, cartel-like profits for decades, securities brokers were now given a much larger market, but also a much more competitive one. One source of competition was brokers such as Charles Schwab who focused on providing discounted services to individuals. As a result, the small partnerships that had populated Wall Street for decades began to fade away, replaced by larger, more heavily capitalized firms that expanded into higher-margin businesses, searching for new sources of profits.[34]

The world of traditional commercial and savings banks was also undergoing changes that would have far-reaching implications. One precipitating factor was the high inflation of the 1970s. High inflation meant higher interest rates, since no one will lend money at 3 percent if inflation is 6 percent. Because the interest paid on traditional savings accounts was capped by Regulation Q, money flowed out of those accounts toward higher-yielding Treasury bills and other forms of short-term debt issued by corporations and governments.[*] Money market funds,[†] invented in 1971, grew from only $3 billion in assets in 1976 to $230 billion by 1982.[35] At the same time as banks were losing their easy source of cheap funds, rising interest rates meant that they were losing money on the mortgages they had made, mostly at fixed rates. Many mortgages made in the early 1970s[36] were still paying only 7 percent even as inflation spiked into double digits at the end of the decade, meaning banks were not even receiving enough interest to make up for inflation. (Homeowners, on the other hand, profited as their debts were inflated away—helping to convince a generation of Americans that houses were the best investment they could possibly make.)

These economic shifts primarily affected savings and loan associations (S&Ls), which were more exposed to mortgages than commercial banks. But at the time, the S&Ls—not the Wall Street investment banks—and their lobbying organization, the United States League of Savings Institutions, were a powerful political force with influence on both sides of the political aisle. Although individually small, they had a favorable public image (in a country that professes to live by small-town values), they were located in virtually every congressional district, and they benefited from the disproportionate representation of rural states in the Senate. "When it came to thrift matters in Congress, the U.S. League and many of its affiliates were the de facto government," said former Federal Home Loan Bank head Edwin J. Gray in 1989.[37]

In response to S&L pressure, Congress passed the Depository Institutions Deregulation and Monetary Control Act of 1980, which phased out Regulation Q, enabling banks to compete for deposits by paying higher interest rates—in the process eliminating one pillar of the "boring banking" business model. No longer able to rely on an artificially low cost of money, banks would have to seek new sources of revenue in new businesses. The bill eased this shift by allowing S&Ls to expand from home mortgages into a range of riskier loans and investments, making it easier for them to make the mistakes that produced the S&L crisis later in the decade. The bill also overrode any state laws restricting the interest that could be charged on first mortgages—meaning that banks could charge whatever interest rates the market would bear.[38]

By 1980, the traditional business models of both investment and commercial banking were eroding in the face of macroeconomic changes and the first waves of deregulation. As historian Charles Geisst wrote of Wall Street, "A turning point had been reached on the Street.… The more placid days of the past were gone forever."[39] There was still no coherent program or ideology that laid out what the financial services industry should look like and what its relationship to the government should be. But that was changing.

At the time, a movement was growing in the halls of America's leading universities that would help transform the financial sector. This movement was the discipline of academic finance, pioneered by economists such as Paul Samuelson, Franco Modigliani, Merton Miller, Harry Markowitz, William Sharpe, Eugene Fama, Fischer Black, Robert Merton, and Myron Scholes, most of whom went on to win the Nobel Prize. These scholars brought sophisticated mathematics to bear on such problems as determining the optimal capital structure of a firm (the ratio between debt and equity), pricing financial assets, and separating and hedging risks.[40]

Academic finance had a tremendous impact on the way business is done around the globe. For example, research on capital structure contributed to a significant increase in indebtedness by corporations.[41] (Debt provides leverage, and therefore increases expected returns along with risk.) It also expanded the market for advising corporations on their funding strategies—a lucrative opportunity investment bankers quickly seized. Similarly, the quantitative study of financial markets helped bankers identify a new universe of ways to make money. New methods for calculating the relative value of financial assets made possible arbitrage trading, where traders sought out small pricing discrepancies that, in theory, should not exist; by betting that the market would make these discrepancies disappear, they could make almost certain money. The Black-Scholes Model (developed by Black, Scholes, and Merton) provided a handy formula for calculating the price of a financial derivative, and in the process gave rise to the derivatives revolution.

Thus academic finance produced important tools that would create new markets and vast new sources of revenues for Wall Street. But it was perhaps even more important for the ideology it created. A central assertion of the academic finance movement in the 1960s and 1970s became known as the Efficient Market Hypothesis: precisely because traders are looking for and exploiting inefficiencies in asset prices, those inefficiencies cannot last for more than a brief period of time; as a result, prices are always "right." As outlined by Eugene Fama in 1970, the Efficient Market Hypothesis comes in a weak form, a semi-strong form, and a strong form. The weak form holds that future prices cannot be predicted from past prices; the semi-strong form holds that prices adjust quickly to all publicly available information (meaning that by the time you read the news in the newspaper, it is too late to make money on the news); and the strong form holds that *no one* has any information that can be used to predict future prices, so market prices are always right. At the time, Fama argued, with empirical evidence, that the weak and semi-strong forms were correct. He acknowledged that there are exceptions to the strong form—exchange floor traders and corporate insiders do have information they can profit from—but found no evidence that anyone else (mutual fund managers, for example) is able to "beat the market" through better information or analysis.[42]

Despite Fama's caveats, the strong form became the intellectual justification for financial deregulation. If a free market will always produce fundamentally correct asset prices, then the financial sector can be left to its own devices. This principle applies directly to securities and derivatives; for example, if a municipality buys an interest rate swap from an investment bank, it must be getting a good deal, since the price it pays is set by the "market" (even if the transaction is negotiated privately between the parties). It applies more broadly to the fees charged for financial services; if the penalty interest rate on a credit card is 30 percent, that must be the true price of the risk that the card issuer is taking on that customer. And conceptually, it even applies to compensation in the financial sector; if a trader takes home a $5 million bonus at the end of the year, that must be the true value of his labor. (Or, as Goldman Sachs CEO Lloyd Blankfein recently asserted in defense of his bankers' high pay, "If you examine our practices on compensation, you will see a complete correlation throughout our history of having remuneration match performance over the long term.")[43]

These were not mathematical consequences of the Efficient Market Hypothesis, but they flowed naturally from it. The basic belief was that if a financial transaction was taking place, it was a good thing. This belief reflects a general economic principle; given perfectly rational actors with perfect information and no externalities, all transactions should be beneficial for both parties. But few economists ever believed that these assumptions actually held in the real world. And over the next few decades, dozens of leading economists such as Joseph Stiglitz, Robert Shiller, and Larry Summers set about knocking holes in the Efficient Market Hypothesis.[44] Brad DeLong, Andrei Shleifer, Summers, and Robert Waldmann created a model showing that "noise trading can lead to a large divergence between market prices and fundamental values."[45] Even Fischer Black (of Black-Scholes fame) agreed. At the 1985 meeting of the American Finance Association, he argued that it was impossible to differentiate between noise and information, and hence impossible to determine who was a noise trader and who was an information trader. Consequently, prices could wander far away from fundamental values for indefinite periods of time.[46]

The Efficient Market Hypothesis did not develop in a vacuum; it was in the vanguard of a broad movement in economics

arguing for decreased regulation and increased liberalization of markets. By the 1990s, there was also an emerging consensus that developing countries should abandon restrictions on the flow of capital and open their economies up to foreign money. The argument, as advanced by Stanley Fischer, then second-in-command at the International Monetary Fund, was that "free capital movements facilitate a more efficient global allocation of savings, and help channel resources into their most productive uses, thus increasing economic growth and welfare," providing benefits that would outweigh any risks.[47] Again, there were important skeptics. Jagdish Bhagwati argued in 1998 that trade in dollars was not the same as trade in goods, because free capital flows would generate financial crises whose potential costs needed to be taken into account.[48] But the belief in free movements of capital, like the belief in efficient markets, became strong enough in some circles to shrug off the need for empirical justification.[49]

The Efficient Market Hypothesis, like the doctrine of free capital flows, provided ready ammunition for anyone who wanted to argue that banks should be allowed to do as they pleased, that financial innovations were necessarily good, and that free financial markets would always produce optimal social outcomes. Even so, it might have remained only a cry in the academic wilderness or an esoteric Wall Street doctrine. But it had the fortune of being in the right place at the right time—of coinciding with a once-in-a-generation shift in the American political climate.

The election of Ronald Reagan marked a crucial turning point in American political history. Although Richard Nixon had already shown how to build a new Republican majority by capitalizing on resentment against Lyndon Johnson's Great Society and the culture of the 1960s, it was Reagan who gave that movement a usable political ideology. Although Jimmy Carter had overseen the beginnings of deregulation with airlines, railroads, and trucking, it was more a topic for policy wonks than for the broader electorate; drawing in part on the ideas of economist Milton Friedman, Reagan made deregulation an ideological crusade.[50] Like many successful leaders, Reagan managed to bring together many conflicting movements and beliefs in his coalition. But his central message, as he said in his first inaugural address, was that "government is not the solution to our problem; government is the problem."[51] According to Reagan, making government smaller and weaker would not only increase personal freedom, it would unleash the creativity and productivity of the private sector.

Reagan fought this battle on many fronts. He cut taxes in an unsuccessful attempt to "starve the beast"—force government to shrink by cutting its funding. He reduced funding to regulatory agencies, hoping to achieve through understaffing what he could not pass through Congress. He installed people who had no interest in regulation at the head of major regulatory agencies. Faced with a Democratic majority in the House of Representatives through his entire presidency, he was unable to fully achieve his goal of dismantling government regulation, but he set the tone for both Republican and Democratic administrations that would follow. (Reagan's ascent to power also closely followed the formation of Margaret Thatcher's first government in the United Kingdom in 1979; Thatcher's deregulatory policies helped unleash the forces of financial innovation in London, with similar results.)

For the financial sector, Reaganism meant breaking down the rules that constrained the activities of financial institutions. As his first treasury secretary (and later chief of staff), Reagan named Donald Regan, the Merrill Lynch CEO who had championed deregulation of brokerage commissions and sought to make Merrill into a diversified financial services company. It was not unusual for a treasury secretary to come from the banking industry. But it was unusual for a treasury secretary to embrace a deregulatory agenda as broad as the one Regan espoused. In an October 1981 interview, he said that his top priority was "the deregulation of financial institutions … trying to deregulate as quickly as possible in the field of interest rates, mandatory ceilings, things of that nature."[52]

The savings and loan industry, still struggling with high interest rates and overreliance on mortgage lending, presented an opportunity for the new administration to test out its theories. In 1982, Congress passed the Garn–St. Germain Depository Institutions Act—hailed by President Reagan as "the first step in our administration's comprehensive program of financial deregulation"[53]—which lifted many regulations on the savings and loan industry, allowing them to expand further into new businesses, such as commercial lending and investing in corporate bonds (including junk bonds), to compensate for the collapse of the "boring banking" business model.[54] In addition, the bill authorized state-chartered banks to offer mortgages with adjustable rates[55] (national banks had been able to offer adjustable rate mortgages since the previous year)[56]—a central feature of the last twenty-five years of innovation in residential lending—and relaxed other constraints on mortgage lending for national banks. The following year, acting under the authorization granted by the bill, the Office of the Comptroller of the Currency lifted all restrictions on loan-to-value ratios (the percentage of a house's appraised value that could be borrowed), maturities (fifteen years, thirty years, etc.), and amortization schedules (meaning that banks could offer mortgages where the principal balance went up over time).[57] The Garn–St. Germain Act also made it easier for banks to operate across state borders by allowing interstate mergers between banks and S&Ls.[58]

The Reagan administration's willingness to help the banking industry also extended to the new innovations that were beginning to take hold on Wall Street. Lewis Ranieri, one of the legendary traders at Salomon Brothers, worked directly with

administration officials to create a new market for mortgage-backed securities.[59] In 1968, the federal agency Ginnie Mae had begun securitizing mortgages—buying mortgages from lenders, combining them in pools, and issuing securities backed by those pools to the lenders (who could then sell them to investors).* The principal on these mortgages (but not the risk that borrowers might prepay) was guaranteed by Ginnie Mae, and therefore by the U.S. government. This guarantee insulated banks from the risk of default by their borrowers and also provided a way to attract money from a wide range of investors to the housing market. In the 1970s, Salomon attempted to create its own mortgage-backed securities out of Bank of America mortgages, but ran into problems with tax laws and with state regulations.

The solution to Salomon's problem was a new bill, the Secondary Mortgage Market Enhancement Act of 1984, which Ranieri helped create and defended before Congress.[60] This bill cleared away the tax issues and state regulations that had hampered Salomon's earlier efforts, giving investment banks the ability to buy up virtually any mortgages, pool them together, and resell them in slices with varying levels of risk. Securitization was made even easier when the Tax Reform Act of 1986 created the Real Estate Mortgage Investment Conduit, or REMIC, which created tax advantages making mortgage-backed securities more attractive. These new laws were unequivocally good for the investment banks, which gained a new market from which they could earn millions of dollars in fees. In return, they were supposed to increase the flow of money into the housing sector, making it easier for people to buy houses. The new market for private mortgage-backed securities also helped commercial banks and S&Ls, which could now pass on the risk of their fixed rate mortgages (which lose value if interest rates increase) to investors in the new securities.[61]

These legislative victories showed the growing influence of Wall Street, but they also depended on Wall Street's ability to wrap itself in the ideology of homeownership—the idea that making it easier for people to buy houses is always a good thing. In contrast to the thrifts, the major commercial and investment banks did not make major gains in the 1980s, despite the friendly attitude of the Reagan administration. Major legislation to break down the Glass-Steagall barrier fell victim to Democrats in Congress. (It also faced opposition from some investment banks, which did not want commercial banks invading their turf.) The Financial Institutions Deregulation Act of 1983, which would have allowed bank holding companies to expand into securities and insurance, died in Congress.[62]

Comprehensive deregulation was also derailed by the savings and loan crisis, which worsened steadily through the 1980s. As it turned out, the Garn–St. Germain Act, by allowing S&Ls to expand into new businesses, prompted many of them to gamble on high-risk investments. S&Ls lacked experience in these businesses, as did their regulators, and over 2,000 banks failed between 1985 and 1992, with a peak of 534 in 1989. (By comparison, only seventy-nine banks failed during all of the 1970s.)[63] Ultimately, over one thousand people were indicted and thrifts suspected of fraud cost the government over $54 billion.*[64]

When Ronald Reagan left office, his program to deregulate the financial sector remained incomplete. The industry still faced significant constraints, such as limits on interstate banking and the Glass-Steagall separation of commercial and investment banks. But although his ambitions remained unfulfilled, Reagan had transformed academic theories and policy prescriptions into a potent ideology that would play a major role in political discourse for at least the next two decades. The collapse of much of the communist bloc beginning in 1989 lent further support to the idea that free market capitalism was the right answer to any question.

EXCITING BANKING

The basic principle behind any oligarchy is that economic power yields political power. The legislative failures of the Reagan administration showed that, in the 1980s, Wall Street did not yet hold sway in Washington. While academic finance provided the intellectual justification for financial nonregulation and the Reagan Revolution provided the political ideology of weak government, these would have mattered less had finance remained simply one industry among many. Instead, the banking industry went through a revolution of its own—one aided in part by academic theories and incipient deregulation, but largely driven by the creativity and competitiveness of a generation of talented bankers. Their serial innovations created the new money machines that fueled the rapid, massive growth in the size, profitability, and wealth of the financial sector over the last three decades—all of which helped Wall Street become a dominant political force in Washington.

This process began in the 1970s, when Michael Milken, a trader at Drexel Burnham Lambert, had the insight that "junk bonds"—bonds that were rated below "investment grade" by the credit rating agencies*—were generally underpriced, either because investors had an irrational aversion to them or because they lacked a liquid market in which to trade them. He capitalized on that market inefficiency, building an operation that dominated the trading and sales of junk bonds. By creating a large, liquid market for junk bonds—which grew from $6 billion in 1970 to $210 billion in 1989[65]—he made it easier for companies to raise money and opened up vast new opportunities for investment banks to generate profits by underwriting, selling, and trading these formerly neglected bonds. By making it easy to raise large amounts of money quickly, junk bonds also made possible the leveraged buyout craze of the 1980s, in which acquirers would pay for acquisitions by issuing large amounts of new debt. Those acquisitions, in turn, generated huge fees for the investment banks that advised the companies engaged in those transactions and also underwrote and sold the necessary debt. They also left companies struggling with huge debt burdens, often requiring painful restructuring and sometimes leading to bankruptcy.

In the 1980s, the Securities and Exchange Commission and the U.S. Attorney's Office for the Southern District of New York (led by Rudy Giuliani) launched investigations of Milken and Drexel Burnham Lambert for insider trading, securities manipulation, and fraud. The investigations eventually led to convictions for both Milken and his employer for securities and reporting violations.[66] But junk bonds—rebranded as "high-yield" bonds—remained a popular form of financing, with over $600 billion in new bonds issued by U.S. corporations from 2003 through 2007.[67] Equally important, investor demand for higher-yield, higher-risk bonds remained strong—driving the recent boom in mortgage-backed securities, especially as returns on Treasury bonds fell to historic lows in the past decade.

The private mortgage-backed securities invented by Lewis Ranieri at Salomon Brothers, with an assist from the federal government, had even larger implications for the future than Milken's creation of the junk bond market. Without securitization, banks generally either held on to the mortgage loans that they made or sold them on the secondary market to Fannie Mae or Freddie Mac—government-sponsored enterprises that provided liquidity to the housing market. By buying mortgages, guaranteeing their principal payments, and turning them into mortgage-backed securities, Fannie and Freddie provided funding for banks to make more mortgages and absorbed some of the risk of the market. Because whole mortgages were difficult to trade (since every mortgage is unique), the number of transactions generated by each mortgage was small.

Securitization created many new ways for banks to profit. For the banks making the initial mortgages, securitization created a new market for their loans, making it easier for them to recover their cash and lend it out again to another borrower, boosting volume. Investment banks had three new ways to make money. They could take fees out of each securitization that they created; they could earn fees selling the new mortgage-backed securities to investors; and they could earn fees (or trading profits) by trading these securities. In each case, the revenues available depended on the volume of mortgage-backed securities. The total volume of private mortgage-backed securities (excluding those issued by Ginnie Mae, Fannie Mae, and Freddie Mac) grew from $11 billion in 1984 to over $200 billion in 1994 to close to $3 trillion in 2007.[68] In addition, once mortgage securitization had caught on, investment banks looked for any other financial assets they could turn into securities—credit card debt, student loans, anything that paid a more or less steady stream of cash flows—further expanding the market.

While mortgage securitization was good for the banks that originated the mortgages and turned them into securities, it was a mixed blessing for everyone else. On the one hand, by attracting additional investors to the mortgage market, it expanded the pool of money available to people who wanted to buy houses. On the other hand, it made possible the "originate to distribute" business model, in which lenders could make profits lending money to people who could not pay it back, making mortgage defaults and foreclosures more likely. Under this model, the risk of default is passed downstream to the investors buying the mortgage-backed securities, who therefore become responsible for policing the quality of the underlying loans; instead of having to make sure that borrowers were likely to pay them back over the next thirty years, lenders could be paid back immediately when they sold off the mortgages for securitization. When it turned out that investors had no idea what risks they were taking on, the result was the collapse of a housing bubble larger than any in recorded American history.

In addition to mortgage-backed securities, Salomon Brothers also pioneered arbitrage trading, which took a variety of forms. For example, traders could make certain money by finding two securities that should but did not have the same value—say, U.S. Treasury bonds maturing in August 2040 and September 2040—buying one, selling the other,* and waiting for their prices to converge. Or they could achieve the same goal by buying the interest payments and the final principal payment on a 30-year bond separately while selling the whole 30-year bond (including interest and principal) for a higher price. In general, such trades make money in one of two ways. Either there is a complex product, often involving embedded options, that other people in the market do not know how to value correctly, or there is a regulation that creates a market inefficiency that can be exploited. In any case, under ordinary market conditions, arbitrage opportunities are close to free money—at least until the number of competitors mimicking a particular strategy drives its profitability down to zero—a far cry from the traditional business of lending money and taking the risk that it might not be paid back.

Although Salomon pioneered quantitative arbitrage trading, the practice soon spread to other investment banks, causing a huge flow of talent into Wall Street (significantly driving up the mathematical aptitude shown on the Philippon-Reshef skill curve) and leading to vast growth in banks' proprietary trading activities (trading on their own account, rather than executing trades for clients).* Its popularity also fueled the rapid growth of hedge funds (lightly regulated investment funds open only to institutions and rich individuals), which grew collectively from less than $30 billion in assets under management in 1990 to over $1.2 trillion in 2005,[69] with estimates over $2 trillion by 2008.[70] Arbitrage became a staple trading strategy of many hedge funds. And because hedge funds rely on investment banks to execute their trades, the growth of hedge funds provided another source of revenue for the banks.

But while it made the hedge funds and the investment banks plenty of money, arbitrage trading had two other effects. Because hedge funds are largely unregulated, large risk exposures were building up outside the view of the financial regulators. And because arbitrage spreads are typically very thin—pricing inefficiencies tend to vanish as traders take advantage of them—making significant profits required large amounts of borrowed money. This leverage was the reason why some proprietary trading operations lost large amounts of money during the 1997–1998 emerging markets crises when prices failed to converge as expected—leading even Salomon Brothers to largely disband its arbitrage team.[71]

The fourth money machine of modern finance—after high-yield debt, securitization, and arbitrage trading—was the modern derivatives market. While commodity futures contracts (in which, for example, a farmer commits to sell wheat in the future for a pre-specified price) had been around for centuries,* the market for financial derivatives remained small until the early 1980s, largely because traders—or, more accurately, the managers responsible for keeping those traders in line—had no good way of calculating what they were worth. But in the 1970s, the Black-Scholes Model gave banks a new way to calculate the value of complicated derivatives and the hedges they used to protect themselves.†

Wall Street embraced these quantitative models because they made it easier to price and trade derivatives in bulk. Nassim Taleb and Pablo Triana have argued that quantitative models are *worse* at pricing derivatives than the heuristics used by traders from the pre-quantitative era.[72] Nonetheless, the formulas gave banks the confidence to sell growing volumes of increasingly complicated trades to clients, since the models enabled them to keep track of how much money they were making on each one. Mathematical models also made it possible to break down complicated trades into simpler ones, a critical factor in the development of sophisticated financial products.

The modern derivatives revolution began with the invention of the interest rate swap (by Salomon Brothers) in 1981. In this transaction, Company A pays interest at a fixed rate to Company B and Company B pays interest at a floating rate (which can go up or down as economic conditions change) to Company A. Interest rate swaps allow companies to exchange fixed rate payments for floating rate payments, or vice versa—"swapping" interest rate risks between the two parties.‡ Similarly, currency swaps allow companies to swap currency risks by exchanging different currencies (or combinations of currencies). Interest rate swaps can also be combined with currency swaps. These two basic derivatives became popular ways for companies to manage financial or operational risks.

For example, a company might have issued $100 million in bonds on which it has to pay a floating interest rate (like an adjustable rate mortgage). Because it does not want to bear the risk that interest rates will go up, it can buy an interest rate swap from a derivatives dealer. The company will pay a fixed rate—say, 7 percent, or $7 million per year—to the dealer; in exchange, the dealer will pay the company the same floating rate that the company has to pay on its bonds. The net result is that the company now pays $7 million per year whether interest rates go up or down, and the dealer bears the interest rate risk. Currency swaps are similar; for example, a U.S. manufacturer with a multiyear contract in Thai baht might enter into a currency swap in order to lock in a constant future exchange rate and protect itself from the risk that the baht will fall. In either case, these derivatives allow companies to offload risks that they do not want to take onto the financial markets, where presumably some party will take on those risks in exchange for a high expected return. (Because the evolution of derivatives has run ahead of regulatory and accounting rules, derivatives can also serve other purposes, such as helping companies smooth their earnings over multiple periods or reduce their tax bills by deferring earnings into the future.)

By the middle of 2008, the market for over-the-counter (customized) interest rate swaps had grown to over $350 trillion in face value (the amount on which interest is calculated) and over $8 trillion in gross market value.*[73] The derivatives dealers—both investment banks and large commercial banks—were taking a piece of every interest rate swap in fees. Even better, the dealers would typically hedge their exposures; ideally, for every swap with one client, they would conduct an opposite swap with another client, so the two trades canceled out—leaving nothing but fees from both clients.

But ordinary swaps were easy for any derivatives dealer to duplicate, and competition between banks soon drove profit margins down near zero. The solution was to invent newer, more complex versions of interest rate and currency derivatives that were hard for competitors to duplicate—and hard for clients to understand. There were "inverse floaters," whose interest rates went in the opposite direction from market interest rates, souped up with leverage and embedded options. There were interest rate swaps that changed their terms based on currency exchange rates. Each of these trades was a customized combination of bonds, swaps, and options that was virtually impossible for a typical client to accurately value; the dealer would charge a large fee, break the transaction into its component parts, and hedge them individually at a much lower cost.

Derivatives expert Satyajit Das has outlined the abusive economics of these transactions. Describing the mechanics of a typical inverse floater, he wrote, "Chairman Greenspan might wax lyrical about the unbundling of risks but we spent most of our waking hours frantically rebundling the risks and stuffing them down the throats of any investor we could find."[74] Because these derivatives were zero-sum trades—one party's loss was the other's profit—one side could be badly burned. Orange County lost almost $2 billion on inverse floaters and similar trades that treasurer Robert Citron clearly did not understand; real-economy companies such as Procter & Gamble and Gibson Greetings similarly lost tens or hundreds of millions of dollars.[75] But these transactions generated large fees for the dealers; Merrill Lynch alone made $100 million on deals with Orange County.[76]

One crucial innovation in the recent history of derivatives, which played an important role in creating the latest financial crisis, was the credit default swap. A credit default swap is a form of insurance on debt; the "buyer" of the swap pays a fixed premium to the "seller," who agrees to pay off the debt if the debtor fails to do so. Typically the debt is a bond or a similar fixed income security, and the debtor is the issuer of the bond. Historically, monoline insurance companies provided insurance for municipal bonds, and Fannie Mae and Freddie Mac insured the principal payments on their mortgage-backed securities. With credit default swaps, however, now anyone could sell insurance on any fixed income security.

Credit default swaps were invented in the early 1990s by Bankers Trust, but were popularized by J.P. Morgan later in the decade as a way for banks to unload the default risk of their asset portfolios; this enabled them to lower their capital requirements, freeing up money that could be lent out again.[77] Credit default swaps also provide a way for a bond investor to hedge against the risk of default by the bond issuer. But because there is no requirement that the buyer of a credit default swap own the debt in question, these derivatives are also a handy way to gamble on the chances of *any* company defaulting on its debts (similar to buying insurance on your neighbor's house); this quality made them a new type of security that could be minted in infinite quantities and traded, providing another source of profit for derivatives dealers. And as discussed later, they would play a crucial role in greasing the wheels of the securitization machine that grew enormously in size in the last decade.

This explosion of new products created vast new profit-making possibilities for financial institutions. These opportunities were mainly available to a handful of investment banks and large commercial banks that could invest in powerful new computer technology and attract highly trained mathematicians and scientists from leading research universities. These large banks also had the scale required to build full-service derivatives operations that could assemble complex transactions and hedge their component parts. These new businesses helped blur the traditional line between commercial and investment banks, replacing it with a divide between small banks, which continued taking deposits and making loans, and big banks, which could branch out into securitization, proprietary trading, and derivatives.

At the same time, large banks were also growing by invading each other's territories and acquiring smaller rivals. Banks had been trying to get around the restrictions on interstate banking and the constraints of the Glass-Steagall Act for decades. Congress responded repeatedly with legislation limiting bank activities, including the Bank Holding Company Act of 1956, the Savings and Loan Holding Company Act of 1967, and the Bank Holding Company Act Amendments of 1970. Beginning in the 1970s, however, the banks became more aggressive, while Congress's resolve waned.

On the one hand, commercial banks sought to raise money for corporate clients, a traditional function of investment banks. In 1978, Bankers Trust began placing commercial paper (short-term debt) issued by corporations with investors. The Federal Reserve Board of Governors ruled that this practice did not violate the Glass-Steagall Act, opening a loophole that was ultimately (after an initial setback in the Supreme Court) upheld by the D.C. Circuit Court of Appeals in 1986.[78] In 1986, the Federal Reserve opened up another loophole, allowing commercial banks to set up affiliated companies (through a common bank holding company) to deal in specific securities that were off-limits to commercial banks, subject to limits on the revenues earned from those securities. Over the next decade, under the direction of chair Alan Greenspan, the Fed expanded the loophole, which began with municipal bonds, mortgage-backed securities, and commercial paper, to include corporate bonds and equities;[79] the Fed also raised the limit on revenues from the securities business and relaxed rules that enforced a separation between banking and securities operations within a single bank.[80] Commercial banks happily took advantage of the opportunity to plunge into new and esoteric businesses. In 1993, for example, NationsBank created a securities subsidiary, NationsSecurities, which began selling its clients mutual funds that invested heavily in inverse floaters and other complex derivatives; the next year, those funds plummeted in value when rising interest rates caused losses on many derivatives.[81]

On the other hand, investment banks sought to encroach on the territory of commercial banks. In the mid-1970s, for example, Merrill Lynch introduced the cash management account (CMA)—a brokerage product that included a money market account with check-writing privileges. This was a key element in Donald Regan's strategy to provide a full spectrum of financial services; as he said, "I wanted to get into banking, and CMA was the way to do it."[82] Cash management accounts competed directly with traditional savings and checking accounts for deposits, and enabled securities firms to sweep up a larger share of their clients' assets.

Investment banks also benefited from the general shift in financial intermediation (the movement of money from people who have it to people who need it) from banks into the capital markets. Traditionally, households and businesses would put their excess cash in deposit accounts at commercial banks or S&Ls, which would lend the cash out as mortgages and commercial loans. However, the high interest rates of the 1970s convinced investors to move their savings from bank accounts to money market funds, which invested in short-term bonds and commercial paper. Increasing affluence also fed the growth of mutual funds and pension funds, which sought out higher-yield investments. This demand for yield created the opportunity for investment banks to raise money for corporate clients by issuing commercial pa-per and bonds and selling them directly to large institutional inves-tors. Money still flowed from households to corporations, but instead of passing through commercial banks, now it could pass through a money market fund or mutual fund—with a helping hand from Wall Street.

Mortgage-backed securities had a similar effect. Institutional investors bought mortgage-backed securities created by investment banks; the cash flowed to mortgage lenders, who no longer needed to be affiliated with traditional banks, because they did not rely on deposits for funding. This flow of money—from investors to special-purpose entities created by investment banks to nonbank mortgage lenders to homebuyers—bypassed the traditional banking system, escaping traditional banking regulation. Large commercial banks also got in on the action, using securitization to tap the capital markets for funds to complement the money deposited by their banking customers.

As banks created new markets and expanded into new businesses, they inevitably got bigger. But they also got bigger the old-fashioned way: by buying each other. Especially after the Riegle-Neal Interstate Banking and Branching Efficiency Act of 1994 relaxed constraints on interstate banking, a handful of large regional banks rushed to construct coast-to-coast networks. NationsBank bought Boatmen's Bancshares in 1996 and Barnett Bank in 1997 to become the biggest bank holding company in the country, passing Bank of America (which had bought Security Pacific in 1992); then NationsBank bought Bank of America in 1998, and in 2004 the new Bank of America bought FleetBoston (itself the merger of the three largest banks in New England). JPMorgan Chase was the product of the mergers of Chemical Bank and Manufacturers Hanover (1991), First Chicago and National Bank of Detroit (1995), Chemical and Chase Manhattan (1996), Bank One and First Chicago (1998), J.P. Morgan and Chase Manhattan (2000), and JPMorgan Chase and Bank One (2004). Wells Fargo bought First Interstate in 1996 and merged with Norwest in 1998. Wachovia was built out of the mergers of First Union, CoreStates, and Wachovia between 1998 and 2001. The largest financial services conglomerate of all (at the time) was put together by Sandy Weill, who began with Commercial Credit, bought Primerica (which owned Smith Barney) in 1988, added Travelers Insurance in 1993, bought Salomon Brothers in 1997, and finally merged his empire with Citicorp in 1998.

The major commercial banks used acquisitions not only to become bigger, but also to push their way into investment banking. Bank of America bought Robertson Stephens in 1997; NationsBank bought Montgomery Securities in 1997; and Chase Manhattan bought Hambrecht & Quist in 1999. European banks joined in, with Credit Suisse buying First Boston in 1988 and Donaldson, Lufkin & Jenrette in 2000, Swiss Bank Corporation (now part of UBS) buying Dillon, Read in 1997, and Deutsche Bank buying Bankers Trust in 1998. America remained populated with thousands of small community banks. But at the top of the pyramid, a handful of financial juggernauts were scrambling over each other to become as big and as broad as possible, as fast as possible. The goal was to create ubiquitous financial "supermarkets" that could provide the full range of financial services to both retail and corporate customers, anywhere.

In short, the financial sector was getting bigger. Between 1980 and 2000, the assets held by commercial banks, securities firms, and the securitizations they created grew from 55 percent of GDP to 95 percent.[83] Financial sector profits grew even faster, from an average of 13 percent of all domestic corporate profits from 1978 to 1987 to an average of 30 percent from 1998 to 2007.[84] The growth was faster still for the largest banks. Between 1990 and 1999, the ten largest bank holding companies' share of all bank assets grew from 26 percent to 45 percent, and their share of all deposits doubled from 17 percent to 34 percent.[85] And they continued to grow. In 1998, the merged Travelers and Citibank had $700 billion in assets;[86] at the end of 2007, Citigroup had $2.2 trillion in assets, not counting $1.1 trillion in off-balance-sheet assets,[87] even after the spinoff of the Travelers insurance businesses. Bank of America was not far behind, growing from $570 billion after the NationsBank–Bank of America merger to $1.7 trillion at the end of 2007.[88]

The transformation of the financial sector through expansion into new businesses and wave after wave of mergers changed the nature of the industry. At its peak was a handful of megabanks with hundreds of billions or trillions of dollars in assets. All of these banks, whatever their origins, were heavily involved in underwriting securities, manufacturing securities (securitization), trading securities, and trading derivatives. Some of them—the ones with roots in commercial banking, such as Citigroup, JPMorgan Chase, and Bank of America—also had wide-ranging branch operations taking hundreds of billions of dollars of deposits. Others—the traditional investment banks and brokerages such as Goldman Sachs, Morgan Stanley, and Merrill Lynch—chose to avoid the hassle and fixed cost of the deposit-taking business altogether, funding their operations through the capital markets. But these alternatives were simply different strategies to obtain the funds necessary to play in the riskier, more profitable world of modern finance. Although greater size should make banks safer, the largest banks compensated by engaging in riskier activities. In 2004, Gary Stern and Ron Feldman—president and senior vice president of the Federal Reserve Bank of Minneapolis—found that "after becoming larger, banks 'spend' their diversification benefit by taking on additional risk. For example, larger banks hold assets in riskier categories, such as commercial and industrial loans, relative to smaller banks."[89] The goal was to be big *and* to take on risk.

The main divide in the industry was no longer between commercial and investment banks; it was between the megabanks, with their portfolios of businesses that had hardly existed three decades before, and the thousands of traditional banks that still made their money taking deposits and extending loans (although now they were more likely to sell those loans off to be securitized). Federal Reserve governor Daniel Tarullo recapped the story in a 2009 speech:

> The regulatory system accommodated the growth of capital market alternatives to traditional financing by relaxing many restrictions on the type and geographic scope of bank activities, and virtually all restrictions on affiliations between banks and non-bank financial firms. The result was a financial services industry dominated by one set of very large financial holding companies centered on a large commercial bank and another set of very large financial institutions not subject to prudential regulation.[90]

These megabanks, whether based downtown, in midtown, or in North Carolina, were the new Wall Street.

* To create asset-backed securities, a new legal entity buys and holds some assets (such as mortgages) and then issues new bonds that are backed by those assets. So the assets behind asset-backed securities are *in addition to* the assets on the balance sheets of commercial and investment banks.

* Depositing money in a savings account is the same as lending money to your bank; buying short-term commercial paper is lending money to a company; buying a Treasury bill is lending money to the U.S. government. Since interest rates on savings accounts were capped but interest rates on other lending were not, people moved money out of savings accounts into other forms of lending.

†A money market fund is a mutual fund that invests in short-term, liquid debt such as Treasury bills or commercial paper. Although money markets are generally not guaranteed against losing value, they attempt to maintain a share price of $1, which makes them look and function like savings or checking accounts.

* To create a mortgage-backed security (MBS), a large number of mortgages are pooled together; the mortgage-backed securities each have a claim on the payments made on those mortgages. The net effect is that each investor in the

MBS owns a tiny piece of each mortgage, distributing each mortgage's risk of default among a large number of investors.

* The mismanagement and outright fraud that led to these failures were one of the inspirations for George Akerlof and Paul Romer's paper on "looting."

* Bonds are IOUs issued by companies or governments. They are given ratings by credit rating agencies; those ratings are supposed to reflect the probability that the issuer will default on the IOU. "Investment-grade" bonds are those that are highly rated, meaning that there is a small probability of default. "Junk" bonds are any bonds that do not earn investment-grade ratings.

* In financial markets, it is possible to sell assets that you don't actually have, known as selling "short." In a short sale, the seller borrows an asset (say, a share of stock) from Party A and then sells it to Party B; at some point in the future, the seller must buy the asset from someone in order to return it to Party A. The seller is betting that the price will have fallen in the meantime, earning it a profit.

* Arbitrage trading received a tremendous boost from the rapid drop in the cost of computing power. Using computers, banks could search the markets for pricing discrepancies and profit from them, provided that they could finance their positions long enough for prices to converge.

* Simple options—in which the farmer pays a small amount now for the right, but not the obligation, to sell wheat in the future for a pre-specified price—were also common before the 1970s.

† In general, a derivatives dealer (a bank) attempts to hedge its positions; that is, if it sells one client an option to buy yak pelts in the future, it will try to buy an equivalent option from another counterparty so its positions cancel out. To hedge a complex trade that is customized for an individual client, the dealer may have to execute multiple trades with other counterparties, which may result in an imperfect hedge.

‡ The risk of a floating rate liability, such as an adjustable rate mortgage, is that interest rates will go up and your periodic payments will go up. The risk of a fixed rate liability, such as a fixed rate mortgage, is that interest rates in general will go down and you will be stuck paying a high interest rate. Depending on the nature of their business, different parties prefer one type of risk or the other.

* In the interest rate swap example above, the face value, or notional value, is $100 million. However, the amount of money that changes hands is much smaller; if, at the end of a given year, the floating rate is 7.25 percent, then the dealer only pays the company 0.25 percent (the difference between the floating and fixed rates), or $250,000.

“GREED IS GOOD”

The Takeover

> Derivatives have been an extraordinarily useful vehicle to transfer risk from those who shouldn't be taking it to those who are willing to and are capable of doing so.… The vast increase in the size of the over-the-counter derivatives markets is the result of the market finding them a very useful vehicle.
>
> —Alan Greenspan, chair of the Federal Reserve, July 16, 2003[1]

The 1980s came to a close with the peak of the savings and loan crisis. The failure of over 2,000 banks between 1985 and 1992 was by far the largest financial sector mass die-off since the Great Depression.[2] The government bailout of the S&L industry cost more than $100 billion, and hundreds of people were convicted of fraud.[3] In 1990, Michael Milken, the junk bond king, pleaded guilty to six felonies relating to securities transactions. In 1991, Citibank was facing severe losses on U.S. real estate and loans to Latin America and had to be bailed out by an investment from Saudi prince Al-Waleed bin Talal. In 1994, Orange County lost almost $2 billion on complicated interest rate derivatives sold by Merrill Lynch and other dealers; county treasurer Robert Citron pleaded guilty to securities fraud, although no one on the "sell side" of those transactions was convicted of anything. In 1998, Long-Term Capital Management collapsed in the wake of the Russian financial crisis and had to be rescued by a consortium of banks organized by the Federal Reserve.

Scandals are a constant refrain throughout the history of the financial services industry. Particularly severe episodes of wrongdoing often lead to the implementation of new rules that at least close the particular barn door that had been left open in the past; the most important example was the new regulatory scheme created during the Great Depression. The failures and scandals of the late 1980s and 1990s were closely linked to recent deregulatory policies or financial innovations: expansion of savings and loans into new businesses; junk bonds and leveraged buyouts; quantitative arbitrage trading; and over-the-counter derivatives. Someone familiar with the history of the financial system might have expected this record of disaster to lead to greater skepticism of financial innovation and closer oversight of the industry.

Instead, the 1990s witnessed the final dismantling of the regulatory system constructed in the 1930s. The Riegle-Neal Act of 1994 practically eliminated restrictions on interstate banking, allowing bank holding companies to acquire banks in any state and allowing banks to open branches in new states. The Gramm-Leach-Bliley Act of 1999 effectively demolished the remaining barriers separating commercial and investment banking—barriers that had already been significantly weakened during the preceding decade—by allowing holding companies to own subsidiaries engaged in both businesses (as well as insurance).

These laws only confirmed trends that had begun in the 1970s, and signified that the federal government would no longer attempt to resist the desires of the large commercial banks to become national, full-service financial supermarkets. More important, the government turned its back on the new financial products that had recently emerged, refusing to regulate over-the-counter derivatives or to police the new Wild West of mortgage lending that appeared late in the decade. Instead, leading policymakers from Alan Greenspan on down chose to rely on "self-regulation" of financial markets—the idea that market forces would be sufficient to prevent fraud and excessive risk-taking.

Despite the scandals and crises that marked the 1990s, this was the decade when Wall Street translated its growing economic power into political power and when the ideology of financial innovation and deregulation became conventional wisdom in Washington on both sides of the political aisle. The unprecedented amounts of money flowing through the financial sector, increasingly concentrated in a handful of megabanks, were the foundation of the new financial oligarchy. In the United States, however, political power on a national scale is generally not bought through simple corruption—by exchanging money under the table for political favors. Instead, Wall Street used an arsenal of other, completely legal weapons in its rise to power. The first was traditional capital: money, which wielded its influence directly via campaign contributions and lobbying expenses. The second was human capital: the Wall Street veterans who came to Washington to shape government policy and shape a new generation of civil servants. The third, and perhaps most important, was cultural capital: the spread and ultimate victory of the idea that a large, sophisticated financial sector is good for America.[4] Together, these powerful forces gave Wall Street a degree of political influence that no amount of payoffs to corrupt politicians could have bought.

CAMPAIGN MONEY

Money has long played an important role in American electoral politics. The interpretation of the First Amendment to protect the financing of political speech, along with the relative weakness of political parties (compared to other advanced democracies) in enforcing discipline among their members, has made it a requirement for individual legislators to devote considerable time and effort to raising money. The escalating cost of campaigning has increased the importance of money. Between 1974 and 1990, the cost of a seat in the House of Representatives—the average expenses of an election winner—grew from $56,500 to $410,000; from 1990 to 2006, it tripled to $1,250,000 (more than doubling even after accounting for inflation).[5]

The financial sector was a central player in this evolution. The sector was the leading contributor to political campaigns throughout the past two decades. But campaign contributions from the financial sector (including finance, insurance, and real estate) grew much faster than contributions overall, more than quadrupling, from $61 million in 1990 to $260 million in 2006. (After excluding insurance and real estate, the sector still contributed over $150 million in 2006; the second-ranking industry group, health care, contributed only $100 million in 2006.) Over the same time period, contributions from the securities and investment industry *sextupled* from $12 million to $72 million, and that $72 million omits the millions of dollars in contributions from the law firms that served the securities industry. (According to one analysis, from 1998 to 2008, the financial sector spent $1.7 billion on campaign contributions and $3.4 billion on lobbying expenses; the securities industry alone spent $500 million on campaign contributions and $600 million on lobbying.)[6] The largest commercial and investment banks, which stood to gain the most from deregulation and consolidation, were also the largest sources of campaign cash. In 1990, the companies in the banking sector that contributed the most money were Goldman Sachs, Salomon Brothers, Barnett Banks (the largest bank in Florida, bought by NationsBank in 1997), Citibank, J.P. Morgan, and Morgan Stanley; in 2006, they were Goldman, Citigroup, Bank of America, UBS, JPMorgan Chase, and Morgan Stanley.[7]

Money from the financial sector flowed precisely where it could do the most good. After becoming chair of the Senate Banking Committee in 1999, Phil Gramm raised more than twice as much money from the securities industry than from any other industry. In 1998, the securities industry's primary beneficiary in the Senate was Alfonse D'Amato, Gramm's predecessor as chair of the Senate Banking Committee; in 1996, D'Amato trailed only Gramm. More recently, the chair of the Senate Banking Committee, Christopher Dodd, received $2.9 million from the securities industry in 2007–2008—more than three times as much as any other senator who was not a major presidential candidate.[8] The securities industry was also the top donor to Barney Frank, chair of the House Financial Services Committee. And the securities industry's favorite member of Congress over the decades has been New Yorker Charles Schumer, first a member of the House Financial Services Committee and later a member of the Senate Banking Committee (and chair of the Democratic Senatorial Campaign Committee in 2006 and 2008), who has aggressively championed Wall Street over the years.[9]

There is a perpetual debate over whether politicians help their major donors because they want to make sure the money keeps flowing, or whether the donors give the money because they appreciate the politicians' positions. In any case, the 1990s, a period of increasing financial sector contributions, were also the decade when the deregulatory campaign crashed through any remaining congressional opposition. Powerful members of Congress sponsored legislation on the financial sector's wish list. Gramm put his name on the 1999 Gramm-Leach-Bliley Act, which largely repealed the Glass-Steagall separation of commercial and investment banking. Gramm was also the major force behind the Commodity Futures Modernization Act of 2000, which prohibited federal regulation of over-the-counter derivatives. Schumer was a major proponent of Gramm-Leach-Bliley, and in 2001 he and Gramm passed legislation to cut in half fees paid by financial institutions to the SEC.[10] (Gramm left the Senate in 2002 to become a vice chair at UBS Warburg.)

Over the past twenty years, the financial services industry became an extremely powerful lobby in Washington, able to win votes in both Republican and Democratic Congresses. In April 2009, Senator Richard Durbin said, "the banks—hard to believe in a time when we're facing a banking crisis that many of the banks created—are still the most powerful lobby on Capitol Hill. And they frankly own the place."[11] No one thought he was saying anything extraordinary.

When it came to money, however, Wall Street had no particular advantage over other industries, except that it had more of it. And while campaign contributions gave Wall Street influence on Capitol Hill, important decisions elsewhere in Washington are made by appointed officials who do not depend on campaign money. Congress can pass legislation that constrains the activities of financial institutions (or not), but that legislation must be translated into regulations and those regulations must be enforced by the executive branch—either administration officials, primarily in the Treasury Department, or regulators serving in the Federal Reserve or one of an alphabet soup of agencies (SEC, CFTC, OCC, OTS, FDIC, NCUA, and so on).[12]

A second source of Wall Street's political power was its ability to place its people in key positions in Washington. As the big banks became richer, more of their executives became top-tier fund-raisers who could be tapped for administration jobs. More important, as the world of finance became more complicated and more central to the economy, the federal government became more dependent on people with modern financial expertise—which meant people from the big banks and from their most cutting-edge businesses. This constant flow of people from Wall Street to Washington and back ensured that important decisions were made by officials who had absorbed the financial sector's view of the world and its perspective on government policy, and who often saw their future careers on Wall Street, not in Washington.

The core problem in regulation is whether regulators will enforce rules that harm the interests of the industry they oversee, or whether they will be "captured" by that industry, as described in George Stigler's 1971 paper "The Theory of Economic Regulation": "as a rule, regulation is acquired by the industry and is designed and operated primarily for its benefit."[13] Capture does not imply that regulators are corrupt, or that their actions are motivated by their personal interests. By contrast, regulatory capture is most effective when regulators share the worldview and the preferences of the industry they supervise. And as banking insiders gained power and influence in Washington, the positions they held—that complex financial products, free financial markets, and large, sophisticated financial institutions were good for America—became orthodoxy inside the Beltway.

Throughout the past two decades, many senior officials moved back and forth between Wall Street and Washington. This was not a new phenomenon; after all, financial services have been an important part of the American economy for a long time. In the last two decades, however, two things changed. First, as the industry changed, the type of leaders it sent to Washington changed. Instead of people who had grown up managing large commercial banks or traditional investment banking firms, now it was people from the newer, riskier, more profitable businesses who were entering public service. Robert Rubin, President Clinton's first director of the National Economic Council (NEC) and second treasury secretary, began his Goldman Sachs career in risk arbitrage (betting on the likelihood of corporate events, such as acquisitions), branched out into relative value arbitrage (capitalizing on pricing discrepancies between similar securities), and co-headed Goldman's fixed income trading department before becoming co-chair of the firm.[14] Henry Paulson, President George W. Bush's last treasury secretary, headed Goldman Sachs from 1999 to 2006, at a time when its trading operations were the most profitable part of the firm.

Second, the increasingly complex nature of finance changed the balance of power between Wall Street insiders and other economic policymakers. Executives from major financial institutions had always been prized in Washington for their relationships with major corporations in all industries. But as finance became more esoteric and policy questions became more technical, Wall Street experience became even more important. On many issues crucial to the financial sector—such as derivatives, securitization, or capital requirements—all the people with relevant expertise were Wall Street veterans. Financial policy took on the trappings of a branch of engineering, in which only those with hands-on experience on the cutting edge of innovation were qualified to comment. In order to stay informed about what was going on in the world of finance, the government had to borrow people from the major banks, who consequently had disproportionate influence over policy. For example, Frank Newman was CFO at Bank of America before joining Treasury in 1993 as undersecretary for domestic finance and later as deputy secretary. During the controversy triggered by the 1994 derivatives losses of Orange County, he wrote a letter urging Congress to "indefinitely postpone" legislation regulating derivatives. In 1995 he became senior vice chair of Bankers Trust, the derivatives dealer most tainted by the 1994 scandals; he was promoted to CEO in 1996.[15]

Many Wall Street bankers took on major positions in the government during the Clinton and George W. Bush administrations. Besides Rubin and Paulson, Goldman Sachs supplied treasury undersecretaries to both administrations—Gary Gensler under Clinton and Robert Steel (who went on to become CEO of Wachovia) under Bush. Other Goldman alumni included Senator Jon Corzine, a member of the Senate Banking Committee; Stephen Friedman, director of the NEC under Bush and chair of the New York Fed; William Dudley, an executive under Tim Geithner at the New York Fed and later its president; Joshua Bolten, director of the Office of Management and Budget (OMB) and chief of staff to President Bush; and a slew of Paulson advisers at Treasury, including Neel Kashkari, head of the Troubled Asset Relief Program (TARP). Other Wall Street executives in the Clinton administration included Roger Altman of Lehman Brothers and the Blackstone Group (a private equity firm) as deputy treasury secretary and Lee Sachs of Bear Stearns as a deputy assistant secretary and later as assistant secretary

for financial markets.[16]

Rapid change in the financial sector put key regulators in the position to make important decisions affecting the industry, and many of those decisions were friendly to the industry. In 1993, Wendy Gramm, chair of the Commodity Futures Trading Commission (CFTC), issued an order exempting most over-the-counter derivatives from federal regulation; in the same year she was named to the board of directors of Enron, a leading trader of energy derivatives and major supporter of that order.[17] As chair of the CFTC from 1999 to 2001, William Rainer co-authored a report recommending that an existing ban on single-stock futures be lifted;[18] that recommendation was implemented by the Commodity Futures Modernization Act of 2000. In 2001, Rainer became CEO of OneChicago, a new exchange to trade single-stock futures.[19] James Gilleran, former CEO of the Bank of San Francisco, became head of the Office of Thrift Supervision in 2001. During his tenure, the agency became known for its lax regulation of thrifts; Gilleran said, "Our goal is to allow thrifts to operate with a wide breadth of freedom from regulatory intrusion."[20] In 2005, he left to become CEO of Federal Home Loan Bank of Seattle. As a Treasury official during the George H. W. Bush administration, John Dugan led a study that advocated the repeal of interstate banking restrictions and of the Glass-Steagall Act; as a lawyer advising the American Bankers Association, he helped steer the Gramm-Leach-Bliley Act through Congress. In 2005, George W. Bush named Dugan Comptroller of the Currency, in which capacity he helped shield federally chartered banks from state regulators.[21]

The close connections between the private and public sectors were also enhanced by longtime government officials who chose to move to the private financial sector. Michael Froman, a member of Rubin's NEC and then his chief of staff at Treasury, followed Rubin to become an executive at Citigroup. Gerald Corrigan worked at the Federal Reserve for over twenty years, serving as the president of the New York Fed from 1985 to 1993; in 1994 he joined Goldman Sachs, where he became a partner and senior executive in 1996. David Mullins, a former assistant secretary at Treasury and vice chair of the Federal Reserve Board of Governors, resigned from the Fed in 1994 to become a partner in Long-Term Capital Management.

The revolving door not only placed Wall Street veterans in important positions in Washington. It also ensured the development of strong personal relationships between leading bankers and government officials, giving the large banks privileged access to key policymakers, and promoted the spread of the Wall Street worldview in the corridors of political power. The prospect of landing prestigious or high-paying jobs in the financial sector may also have influenced the decisions of regulators and administration officials, who may have had an incentive not to make enemies among their potential future employers.

But banks also had a more direct means of putting pressure on their regulators—the market for regulatory fees. The Federal Reserve makes the money for its day-to-day operations from its banking activities, and the FDIC makes its money from insurance premiums levied on banks. But the other major regulators, including the Office of the Comptroller of the Currency (OCC) and the Office of Thrift Supervision (OTS), are funded by fees levied solely on the banks that they regulate. And while each regulator nominally had its own sphere of jurisdiction—bank holding companies for the Fed, national banks for the OCC, and so on—financial institutions that fell under multiple regulatory agencies were allowed to select their primary regulator. As a result, regulatory agencies had to compete for funding by convincing financial institutions to accept their regulation, which created the incentives for a "race to the bottom," in which agencies attract "customers" by offering relatively lax regulatory enforcement.

The OTS stood out in this competition. According to William Black, a law professor and former official at the Federal Home Loan Bank Board, "The reputation of the Office of Thrift Supervision was that it was the weakest, and the laxest, and it was indeed outright friendly to the worst of the non-prime lending."[22] American International Group (AIG), a massive insurance company with one of the largest derivatives trading operations in the world, opened a savings and loan—and then chose the OTS as its primary regulator, even though the agency, with its focus on mortgage lending, had no chance of monitoring the risks taken on by AIG's infamous Financial Products division. In 2005, the giant mortgage lender Countrywide, then regulated by the OCC, met with the OTS to discuss switching regulators. According to *The Washington Post,* "Senior executives at Countrywide who participated in the meetings said OTS pitched itself as a more natural, less antagonistic regulator than OCC and that [Countrywide CEO Angelo] Mozilo preferred that. Government officials outside OTS who were familiar with the negotiations provided a similar description."[23] In March 2007, the OTS approved Countrywide's application to convert itself from a bank holding company into a savings and loan holding company in order to fall under the OTS's regulation.[24]

Between the revolving door and the competition for regulatory "business," there was a confluence of perspectives and opinions between Wall Street and Washington that was far more powerful than emerging-market-style corruption. Wall Street's positions became the conventional wisdom in Washington; those who disagreed with them, such as Brooksley Born, were marginalized as people who simply did not understand the bright new world of modern finance. This groupthink was a major reason why the federal government deferred to the interests of Wall Street repeatedly in the 1990s and 2000s.

One of history's curiosities is that this shift happened within a Democratic administration, headed by a president elected largely because of middle-class economic insecurity. Of all the people to migrate from Wall Street to Washington, the most important was Robert Rubin. When Rubin joined the Clinton administration in 1993—having first gained entrance to the party's inner circles through his fund-raising prowess[25]—the transformation of the financial sector into a risktaking, moneymaking colossus was well underway. But the right of big banks to make money free from government intervention was not yet secured. There was still a major force in American politics that was skeptical about Wall Street and the unbridled pursuit of profit: the Democratic Party, which had helped block deregulatory legislation in Congress in the 1980s.

Bill Clinton was elected president in 1992 without any apparent strong opinion of the financial sector. Although his campaign theme was "the economy, stupid,"[26] as a challenger he was able to propose a broad economic platform (including health care reform, a middle-class tax cut, and education spending) without having to take a position on Wall Street. When Clinton took office, his appointments reflected a broad range of views within the Democratic Party. Lloyd Bentsen, a moderate who had spent the past twenty-two years in the Senate, was secretary of the treasury; Roger Altman, from both Wall Street and the Carter administration, was his deputy; Robert Reich, a traditional liberal (in the American sense) was secretary of labor; Laura Tyson, an advocate of industrial policy, was chair of the Council of Economic Advisers; and Rubin was director of the NEC, a new body created by Clinton to coordinate economic policymaking.

The crucial question was whether to increase spending on social programs and follow through on the campaign pledge of a middle-class tax cut, or to balance the budget in order to keep interest rates low. Rubin was a political liberal in many ways, supporting government social programs and opposing the welfare reform bill of 1996.[27] But he believed even more in fiscal responsibility and the importance of building a friendly relationship with the "bond market" in order to provide a foundation for long-term growth. The theory was that the bond market was distrustful of Democratic presidents; if it suspected Clinton of fiscal irresponsibility, it would demand higher yields on U.S. government debt, pushing up interest rates across the economy and stifling economic growth.

At a January 1993 meeting, the Clinton economic team agreed that deficit reduction should be their top priority, in order to establish credibility with Wall Street.[28] (This policy prompted Clinton adviser James Carville to say, "I used to think that if there was reincarnation, I wanted to come back as the President or the Pope or as a .400 baseball hitter. But now I would like to come back as the bond market. You can intimidate everybody.")[29] They were betting that by increasing taxes and bringing budget deficits under control, they could reduce interest rates and stimulate growth. These policy choices approximately coincided with the beginning of one of the longest economic booms in recent history—from 1993 to 2000, annual real GDP growth averaged 3.9 percent, while inflation averaged only 1.8 percent[30]—although other factors probably contributed to the boom, including the increasing use of computer technology and the impact of globalization.

In early 1995, Rubin succeeded Bentsen as treasury secretary, becoming the administration's primary economic policymaker, at a crucial moment for the White House. After its resounding defeat in the 1994 congressional elections, many insiders felt that the Democratic Party needed to turn to the left and advocate more populist economic policies. Rubin, however, favored the administration's centrist course, maintaining a pro-business stance and focusing on deficit reduction. Clinton sided with Rubin, confirming the Democrats' transformation into a market-oriented, business-friendly party that could be trusted by Wall Street.[31]

The ascendancy of the former co-chair of a premier investment bank also sent a signal that the administration would be sympathetic to Wall Street. While big business and big banks could historically count on the support of the Republicans, now they could rely on the Democrats as well. With Rubin in place, the government was unlikely to go after any of the new cash cows the financial sector had created in the last two decades, such as securitization, derivatives, or quantitative proprietary trading.

In addition to shaping the economic policies of the Clinton administration, Rubin mentored a generation of Democratic policymakers who are largely sympathetic with his views. He brought in some key Treasury officials directly from Wall Street, including Gensler from Goldman Sachs (now chair of the CFTC) and Lee Sachs from Bear Stearns (now a counselor to the treasury secretary). In contrast, Rubin's two top protégés did not come from Wall Street, but they largely adopted his perspective on economic and financial issues. Larry Summers, deputy secretary under Rubin and his successor as treasury secretary, was an academic economist and former chief economist at the World Bank. Tim Geithner, assistant secretary and then undersecretary for international affairs, was a career civil servant. But they shared Rubin's opinion that financial innovation and free markets were generally good for America. Summers opposed derivatives regulation even more strongly than Rubin; in his 2003 memoir, Rubin wrote, "Larry characterized my concerns about derivatives as a preference for playing tennis with wooden racquets—as opposed to the more powerful graphite and titanium ones used today."[32] (Summers and Geithner are now director of the NEC and treasury secretary, respectively.) Rubin was also a founder of the Hamilton Project, a centrist study group based at the Brookings Institution, which served as a way station for rising economy policy specialists such as Peter Orszag (now director of the OMB) and Jason Furman (now deputy director of the NEC). The end result was a Democratic policy establishment that no longer took its cues from unions and consumer advocates, but was now open or even

friendly to the positions of Wall Street.

This political realignment was, in many ways, a huge boon to the Democratic Party. "Rubinomics" established the party's credibility in the eyes of the business and financial communities, repairing the damage done by the perceived economic mismanagement of the Carter administration and helping to balance the fund-raising scales against the Republicans. The long boom of the 1990s, whether or not it should be credited to Clinton-era policies, looked especially good when compared to the record of the George W. Bush administration, which saw slower growth (average real GDP growth of 2.2 percent, down from 3.9 percent under Clinton) and declining median income (falling from $52,500 in 2000 to $50,300 in 2008, both in 2008 dollars).[33] The shift of the Republican Party toward "cultural" issues also helped throw more investment banking and hedge fund moguls into Democratic arms.

The story of the Clinton administration demonstrates the key role that influential Wall Street insiders could play in reshaping the landscape of national politics. By 2008, the economic consensus of the Democratic establishment was based on the policies of Clinton, Rubin, and Summers.

In the 1990s, only one figure in the Washington economic elite surpassed Rubin in stature: Alan Greenspan, chair of the Federal Reserve from 1987 until 2006 and one of the most important legacies of the Reagan administration. Although Greenspan was not a Wall Street banker—he headed a New York economic consulting firm for nearly thirty years before becoming Fed chairman—there came to be no truer believer in the ideology of free markets, financial innovation, and deregulation.

Greenspan was a "lifelong libertarian Republican" and a longtime associate of Ayn Rand, the philosopher and novelist who argued for pure laissez-faire capitalism.[34] He believed in both the doctrine of efficient markets and the Reagan Revolution against governmental interference in the economy. He looked forward eagerly to a world without government regulation:

> Regulation is inherently conservative. It endeavors to maintain the status quo and the special interests who benefit therefrom.… With technological change clearly accelerating, existing regulatory structures are being bypassed, freeing market forces to enhance wealth creation and economic growth.
>
> In finance, regulatory restraints against interstate banking and combinations of investment and commercial banking are being swept away under the pressures of technological change.…
>
> As we move into a new century, the market-stabilizing private regulatory forces should gradually displace many cumbersome, increasingly ineffective government structures. This is a likely outcome since governments, by their nature, cannot adjust sufficiently quickly to a changing environment, which too often veers in unforeseen directions.
>
> The current adult generations are having difficulty adjusting to the acceleration of the uncertainties of today's silicon driven environment. Fortunately, our children appear to thrive on it. The future accordingly looks bright.[35]

Greenspan was naturally predisposed to be friendly toward the financial sector and its desire to be left alone by government. As a central banker, he first made his mark injecting liquidity into the financial system to pull the stock market out of its 23 percent fall on Black Monday, October 19, 1987. This was the first example of what came to be known as the "Greenspan put"—the idea that if trouble occurred in the markets, the Fed would come to their rescue.* Greenspan cut interest rates sharply in 1998 following the Russian crisis and in 2001 following the collapse of the Internet bubble, each time helping to cushion the impact of the downturn and arguably pumping up the next bubble. The underlying theory, set out in Greenspan's famous 1996 "irrational exuberance" speech, was that the Fed should not attempt to head off bubbles, but instead should focus on helping the economy recover when those bubbles popped: "[H]ow do we know when irrational exuberance has unduly escalated asset values, which then become subject to unexpected and prolonged contractions as they have in Japan over the past decade? … We as central bankers need not be concerned if a collapsing financial asset bubble does not threaten to impair the real economy, its production, jobs, and price stability."[36] This position was an endorsement of the Efficient Markets Hypothesis and the idea that the Fed should not attempt to determine if prices are accurate, but should leave that function to the markets.

Wall Street appreciated Greenspan's monetary policy, because it meant that he would not raise interest rates preemptively to choke off a boom (unless that boom was also creating higher inflation). But it appreciated his hands-off regulatory policy even more. The Federal Reserve is one of the most important financial regulatory agencies, not only regulating bank holding companies but also enforcing consumer protection laws. But for almost two decades it was led by a man whose faith in financial innovation outweighed any interest he had in regulating the financial sector, and who had entered public life in order to "engage in efforts to advance free-market capitalism as an insider."[37]

For example, Greenspan strongly believed that financial derivatives served a valuable role in dispersing risk throughout the financial system, and that market participants were sophisticated enough to manage the risks created by derivatives. In July 2003, he told the Senate Banking Committee,

> What we have found over the years in the marketplace is that derivatives have been an extraordinarily useful vehicle to transfer risk from those who shouldn't be taking it to those who are willing to and are capable of doing so.… The vast increase in the size of the over-the-counter derivatives markets is the result of the market finding them a very useful vehicle. And the question is, should these be regulated? Well, indeed, for the United States, they are obviously regulated to the extent that banks, being the crucial creators of these derivatives, are regulated by the banking agencies, but not beyond that. And the reason why we think it would be a mistake to go beyond that degree of regulation is that these derivative transactions are transactions amongst professionals.[38]

For Greenspan, the rapid growth of the derivatives market was *proof* that they were socially beneficial. He believed, like many free market purists, that markets are self-regulating, and that as long as market participants have sufficient information, they will be aware of any potential dangers and protect themselves from them, and therefore outcomes in an unregulated market are necessarily good. This attitude even extended to fraud; as Brooksley Born recounted, "He explained there wasn't a need for a law against fraud because if a floor broker was committing fraud, the customer would figure it out and stop doing business with him."[39]

Greenspan dominated the Fed during his tenure, and his views became close to dogma on the Board of Governors. At an August 2005 symposium held by the Kansas City Federal Reserve Bank to honor Greenspan, Raghuram Rajan presented a paper asking in prophetic detail whether deregulation and innovation had increased rather than decreased risk in the financial system.[40] Rajan, then chief economist of the International Monetary Fund, was met with a torrent of attacks by Greenspan's defenders.[41] Fed vice chair Donald Kohn responded by restating what he called the "Greenspan doctrine." Kohn argued that self-regulation is preferable to government regulation ("the actions of private parties to protect themselves … are generally quite effective. Government regulation risks undermining private regulation and financial stability"); financial innovation reduces risk ("As a consequence of greater diversification of risks and of sources of funds, problems in the financial sector are less likely to intensify shocks hitting the economy and financial market"); and Greenspan's monetary policy resulted in a safer world ("To the extent that these policy strategies reduce the amplitude of fluctuations in output and prices and contain financial crises, risks are genuinely lower"). Kohn's conclusion reflected the prevailing view of Greenspan at the time: "such policies [recommended by Rajan] would result in less accurate asset pricing, reduce public welfare on balance, and definitely be at odds with the tradition of policy excellence of the person whose era we are examining at this conference."[42] Larry Summers more directly said he found "the basic, slightly lead-eyed premise of [Rajan's] paper to be misguided."[43]

Besides his considerable powers as steward of U.S. monetary policy and one of the chief regulators of the financial sector, Greenspan also mattered because of his tremendous public stature. As the U.S. economy settled into a long boom with falling unemployment and low inflation, he became probably the world's most famous and respected economist. If Greenspan said that derivatives improved the management of risk and financial innovation was always good, that provided cover for anyone in Washington who didn't know what to think about the issue.

With Greenspan at the Federal Reserve, Rubin and Summers at Treasury, a reliably friendly and compliant set of regulators, and millions of dollars flowing into Congress with each election cycle, Wall Street had friends throughout Washington in the 1990s. Little changed in the following decade under the Bush administration, which believed even more strongly in deregulation. Rarely has one industry enjoyed such unchecked power in Washington.

THE IDEOLOGY OF FINANCE

It is one thing to have important congressmen dependent on your campaign contributions, and to have your own people in key positions of power, and even to have some regulators enthralled by the prospect of lucrative jobs. Those factors alone gave Wall Street tremendous political power. But in addition to these traditional forms of political capital, the major banks amassed another form of power: cultural capital.

Politics is like sales. If you are trying to close a large deal with a major corporation, it helps to have friends on the inside, it helps to have buyers who see their fortunes aligned with yours, and it can even help to dangle the prospect of a high-paying job before the key decision-maker. But it is even better if the buyers really, independently want what you are selling. It is best of all if they believe that buying what you are selling is a symbol of their own judgment and sophistication—that buying your product marks them as part of the informed elite.

Any industry—say, Big Tobacco—can buy friends in Washington, who will work hard behind the scenes to help that industry. But over the last two decades, Wall Street's friends could work in the light of day, as the causes they championed gained an enthusiastic following among elites in Washington and New York (and major European capitals). The idea that a sophisticated, unrestrained financial sector was good for America became part of the conventional wisdom of the political and intellectual class. As a result, deregulation was no longer something to be buried in thousand-page bills—although that did happen—but was instead the focus of celebratory photo opportunities. In June 2003, representatives of three industry organizations joined the vice chair of the FDIC and the director of the OTS to kick off a project to "identify and eliminate any regulatory requirements that are outdated, unnecessary or unduly burdensome." Each of them threatened a symbolic stack of paper documents with a pair of garden shears—except for James Gilleran, director of the OTS, who brought a chainsaw.[44]

Over the past twenty years, finance changed in the public eye from a boring and slightly untrustworthy pursuit to the glistening centerpiece of the modern American economy. In much of the country, suspicion of bankers remained high or even increased with the prosecutions of people from Ivan Boesky and Michael Milken (insider trading) to Henry Blodget (talking up bad stocks). But where it mattered most—on elite academic campuses, in the business and financial media, in think tanks, and in the halls of power in Washington—banking became the latest chapter of the American Dream, the way to make vast riches by working hard and creating innovative new products that would supposedly improve life for everyone.

The positive image of Wall Street had at least three main components. The first was the idea that financial innovation, like technological innovation, was necessarily good. The second was the idea that complex financial transactions served the noble purpose of helping ordinary Americans buy houses. The third was that Wall Street was the most exciting place to be at the turn of the new millennium.

Innovation, in American English, is an unambiguously positive word. Dating back to Benjamin Franklin and Eli Whitney, we like to see ourselves as a nation of creative, resourceful inventors who solve problems through ingenuity and hard work. More recently, when we think of innovation, we think of technology: of Hewlett and Packard in their garage, or Jobs and Wozniak in theirs. And given all the material benefits that technological innovation has given us, it seems logical that financial innovation must be equally beneficial.

The language of innovation has been widely used to describe recent changes in the financial sector. In a 1995 paper, Robert Merton wrote, "Looking at financial innovations … one sees them as the force driving the global financial system towards its goal of greater economic efficiency. In particular, innovations involving derivatives can improve efficiency by expanding opportunities for risk sharing, by lowering transaction costs and by reducing asymmetric information and agency costs."[45] Two years later, Alan Greenspan said,

> The unbundling of financial products is now extensive throughout our financial system. Perhaps the most obvious example is the ever-expanding array of financial derivatives available to help firms manage interest rate risk, other market risks, and, increasingly, credit risks.… Another far-reaching innovation is the technology of securitization—a form of derivative—which has encouraged unbundling of the production processes for many credit services.… These and other developments facilitating the unbundling of financial products have surely improved the efficiency of our financial markets.[46]

As the financial sector became a bigger part of the U.S. economy, the celebration of financial innovation only increased. In 2006, even as he warned about potential risk management challenges generated by derivatives, Tim Geithner (then New York Fed president) said of the current wave of financial innovation,

> These developments provide substantial benefits to the financial system. Financial institutions are able to measure and

> manage risk much more effectively. Risks are spread more widely, across a more diverse group of financial intermediaries, within and across countries.
>
> These changes have contributed to a substantial improvement in the financial strength of the core financial intermediaries and in the overall flexibility and resilience of the financial system in the United States. And these improvements in the stability of the system and efficiency of the process of financial intermediation have probably contributed to the acceleration in productivity growth in the United States and in the increased stability in growth outcomes experienced over the past two decades.[47]

Even in April 2009, after the financial crisis, Greenspan's successor, Ben Bernanke, said, "Financial innovation has improved access to credit, reduced costs, and increased choice. We should not attempt to impose restrictions on credit providers so onerous that they prevent the development of new products and services in the future."[48] The fact that Bernanke, a brilliant and widely respected academic, would sing the praises of financial innovation even after the financial crisis shows the powerful hold this ideology exerted on both economists and policymakers.

Merton and Greenspan's argument about "risk sharing" and "unbundling" added intellectual heft to the ideology of innovation. According to this story, derivatives and securitization have the beneficial effect of spreading risk out among more market participants and allocating specific risks to the people who most want to hold them. Credit default swaps, for example, allow banks to divide up interest rate risk and default risk between different investors. Since all parties are negotiating freely in an open market, these transactions should be good for everyone—and they can be, if those parties know what they are doing. The rebranding of complexity as innovation, however, provided a blanket justification to any new financial products, paving the way not only for the inverse floaters sold to Orange County but for similar products sold to individual investors. Reverse convertibles, for example, are structured notes where the investor gets either a fixed interest rate *or* a share of stock, depending not only on the final stock price but on the path it takes getting there; because of their complexity, few investors are able to value them accurately, making them prey to unscrupulous brokers and banks.[49] ("I was told there was no risk with these," said one retiree who lost over $90,000 on reverse convertibles.)[50]

The ideology of innovation had its skeptics. Warren Buffett famously labeled derivatives "financial weapons of mass destruction" in the Berkshire Hathaway 2002 annual report.[51] In his 2001 book *Fooled by Randomness,* Nassim Taleb argued that modern financial technology underestimated the likelihood of extreme events, with potentially catastrophic implications.[52] Janet Tavakoli's 2003 book, *Collateralized Debt Obligations and Structured Finance,* discussed the potential problems involved in securitization, including the risk of fraud.[53] And decades before, Hyman Minsky had pointed out the role of innovation in enabling financiers to increase their profits at the risk of destabilizing the economy.[54] They could all be ignored as long as market conditions remained benign. But the Merton-Greenspan "risk unbundling" story was proven horribly wrong by the financial crisis that began in 2007—caused in part by innovative products that made it possible for financial institutions and investors to take on massive amounts of risk hidden inside AAA-rated securities that later plummeted in value. Eventually even Greenspan was forced to admit his mistake in a congressional hearing.[55]

The recent orgy of financial innovation turned out so badly because financial innovation is *not* like technological innovation. There are financial innovations that do benefit society, such as the debit card. And derivatives, as discussed earlier, can be useful tools to help companies hedge their operational risks. But there is no law of physics or economics that dictates that *all* financial innovations are beneficial, simply because someone can be convinced to buy them. The core function of finance is financial intermediation—moving money from a place where it is not currently needed to a place where it is needed. The key questions for any financial innovation are whether it increases financial intermediation and whether that is a good thing.

Much recent "innovation" in credit cards, for example, has simply made the *pricing* of credit more complex. Card issuers have lowered the "headline" price that they advertise to consumers while increasing the hidden prices that consumers are less aware of, such as late fees and penalty rates. These tactics have increased the profits of credit card issuers, but have not increased financial intermediation—except insofar as they helped consumers underestimate the cost of credit and therefore borrow excessive amounts of money.[56]

Innovation that increases the availability of credit can also be harmful. The stated-income mortgage, where loan originators explicitly did not verify borrowers' incomes, made it easier for some people to borrow more money to buy houses, but also served as an invitation to fraud (by both borrowers and mortgage brokers) and left many borrowers unable to repay their mortgages. Investments can be economically value-creating or value-destroying; when financial intermediation increases to the point where value-destroying investments are being funded, financial innovation is doing more harm than good.

But in the 1990s and 2000s, the theory of risk unbundling and diversification reigned largely unchallenged in Washington; people who didn't subscribe to it could be written off as ignoramuses who failed to understand the elegance of modern finance. Merton and his colleague Myron Scholes, after all, won the Nobel Prize in economics in 1997 (a year before the collapse of their hedge fund). It also helped that financial services were one arena where U.S. firms were in the international vanguard, inventing most of the new products and markets of the past few decades. With the trade deficit in manufactured goods widening

continuously, structured securities were one of our most attractive exports, especially to European banks and investors looking for higher-yield investments. After the Internet bust, Wall Street became our most prestigious economic center, and keeping it that way became an end in itself. As Senator Schumer said in 2007 of existing financial regulations, "We are not going to rest until we change the rules, change the laws and make sure New York remains No. 1 for decades on into the future."[57]

The New American Dream was to make tens of millions on Wall Street or as a hedge fund manager in Greenwich, Connecticut. But it was also connected to the Old American Dream—to own a house of one's own. In the last thirty years, the Wall Street ideology borrowed heavily from the older, more deep-rooted American ideology of homeownership, which became widely accepted after World War II as government programs and economic prosperity made possible a homeowning middle class. Wall Street co-opted this ideology to justify the central place of modern finance in the economic and political system, especially as the homeownership rate climbed from 64 percent, where it sat from 1983 to 1994, to a high of 69 percent in the 2000s.[58]

The ideology of homeownership has its roots in two sources. The first is the idea that homeownership is intrinsically good—it encourages individual responsibility, provides financial security, promotes community attachment, encourages people to take care of property, and so on. This ethos may have something to do with the important place of independence and self-reliance in the constellation of American values. Or it may be the product of various government policies designed to encourage homeownership. There may also be an element of truth to this idea; homeownership is generally thought to create positive externalities, since homeowners are on average more likely to devote effort to improving their communities. After reviewing other empirical studies and doing their own analyses, Edward Glaeser and Jesse Shapiro conclude:

> [T]here is a limited body of evidence suggesting that homeownership creates positive spillovers for near neighbors. Homeowners do appear to be more active citizens. They vote more. They take better care of their homes. Houses that are surrounded by homeowners are worth a little more than houses that are surrounded by renters.[59]

However, much of the positive effect of homeownership is due not to ownership itself, but to other factors that differentiate owners and renters. In another paper, Glaeser and Denise DiPasquale found that "almost one-half of the effect of homeownership disappeared when we controlled for the time that the person had lived in the home."[60] William Rohe and Michael Stegman compared a sample of low-income homebuyers with similar low-income renters over time and found that the homebuyers were less likely to engage in informal neighboring, more likely to participate in block associations, and no more likely to participate in other types of community associations.[61] Alyssa Katz concludes, in *Our Lot,* "scholars found that once they set aside the various traits that tend to determine whether someone chooses to own or rent one's home, homeowners and tenants really aren't that different."[62]

The second source of the ideology of homeownership is the idea that owning a home is the best possible investment for a household. Although widely believed, this idea is questionable at best: absent government incentives, betting several times your entire net worth not only on a single type of asset, but on a single building and plot of land, is almost the worst investment you could make after accounting for risk. Many families have made money from housing price appreciation (particularly if they took out mortgages before the inflation of the 1970s), but their high returns are primarily due to the high leverage built into a typical mortgage—leverage that produces massive defaults and foreclosures in a housing downturn such as the one that began in 2006. The things that make housing attractive as an investment are favorable government policies, such as the mortgage interest tax deduction, in which the government subsidizes mortgages for homeowners.*

In any case, homeownership ranks alongside motherhood and apple pie in the firmament of American values, and helping more people buy houses is almost always seen as a good thing. Lewis Ranieri capitalized on this ideology when he created the market for private mortgage-backed securities beginning in the late 1970s. Mortgage-backed securities would enable lenders to replenish their coffers by tapping the entire world of securities investors, expanding the amount of credit available to homeowners and thereby allowing more people to buy houses at lower interest rates. At a congressional hearing, Katz recounts. "Ranieri promised that putting private bankers and their sales forces in charge of mortgage securities would save borrowers half a percent on every loan."[63] Congress agreed; in a 1983 report, the Senate Banking, Housing, and Urban Affairs Committee warned that without expanding the market for private mortgage-backed securities, "mortgages would cost more and be more costly to obtain."[64] Ranieri hitched the mortgage-backed securities market to the cause of expanding homeownership, ensuring its political success.

In the 1990s and 2000s, another financial innovation appeared on the scene with the potential to extend the dream of homeownership to millions more households: subprime mortgage lending. (Subprime lending had been around for decades, but only recently became a major source of money to buy houses, as opposed to refinancing them.)[65] During the housing boom, lenders scrambled to offer mortgages to people who would never have qualified for them before the boom. These were high-cost loans to people with no verified ability to pay them off, which made sense only assuming that continually rising housing

prices would leave the lenders with valuable collateral in case of default. These practices looked a lot like predatory lending. But the mortgage lenders and the investment banks that bought and securitized their mortgages justified such activity on the grounds that it promoted homeownership. "Our innovative industry has created a great way to expand homeownership by offering loans to those who can make payments, but who don't qualify for 'A' paper because of poor credit or bankruptcy," said Ron McCord, former president of the Mortgage Bankers Association, in 1997.[66]

And the story stuck. Not only did the federal government make no attempt to regulate subprime lending, but it even became a cheerleader for the subprime boom. The Clinton administration had made an expansion of homeownership a central part of its economic strategy; in 1995, Clinton set a goal of a 67.5 percent homeownership rate[67] at a time when the actual rate was 65 percent (it would peak the next decade at 69 percent).[68] In order to help meet this goal, the Department of Housing and Urban Development mandated that Fannie Mae and Freddie Mac—the giant government-sponsored enterprises that provided funding for the mortgage market—had to devote 42 percent of their money to loans to low- and moderate-income households. That target was increased to 50 percent in 2000 and then to 56 percent in 2004.[69]

Growing real household incomes helped a bit in the mid-1990s. But beginning in 1997, the growth of housing prices outstripped income growth; after 1999, real median household income *fell* for five consecutive years as housing prices soared.[70] Under these circumstances, as George W. Bush not only continued his predecessor's support for increased homeownership but even made the "ownership society" a centerpiece of his political message, the only thing that could keep the homeownership boom going was expanded availability of credit.

Alan Greenspan became an eloquent spokesman for the synergy between financial innovation and homeownership. In a 2005 speech discussing the impact of new financial technology, he said,

> Improved access to credit for consumers, and especially these more-recent developments, has had significant benefits. Unquestionably, innovation and deregulation have vastly expanded credit availability to virtually all income classes. Access to credit has enabled families to purchase homes, deal with emergencies, and obtain goods and services. Home ownership is at a record high.[71]

The only caveat that Greenspan gave was that the increase in credit availability made it more important to ensure widespread financial education.

For anyone who had doubts about the value of financial innovation and the importance of Wall Street, the ideology of homeownership provided easy assurance. The idea that complex securities could help low- and middle-income families own homes was especially attractive to Democratic congressmen and officials who might ordinarily be distrustful of mortgage lenders and investment bankers, and helped seal off Wall Street's new money machine from criticism.

The economic and political elites could agree that innovation was good, and that homeownership was good. But the ideology of finance went beyond the idea that Wall Street was good for America. Banking was not only the center of the U.S. economy—it became cool, seductive, and even sexy.

In 1987, Tom Wolfe's novel *The Bonfire of the Vanities* introduced the term "Master of the Universe" to American culture, in the form of multimillionaire investment banker Sherman McCoy, who lived in "the sort of apartment the mere thought of which ignites flames of greed and covetousness under people all over New York and, for that matter, all over the world."[72] Although the term was used sarcastically, and McCoy turns out badly in both the human and financial senses, the image of the swashbuckling, super-rich banker engaged in transactions too complex to be understood by ordinary mortals was born.

Also in 1987, Oliver Stone's movie *Wall Street* was released, with its memorable antihero, corporate raider Gordon Gekko (played by Michael Douglas). Although the movie's story shows the corruption and ultimate downfall of Gekko, it is remembered for his "Greed is good" speech, which justified the pursuit of money above all else. As screenwriter Stanley Weiser wrote recently, many people would later tell him the movie made them *want* to work on Wall Street: "A typical example would be a business executive or a younger studio development person spouting something that goes like this: 'The movie changed my life. Once I saw it I knew that I wanted to get into such and such business. I wanted to be like Gordon Gekko.' "[73]

Liar's Poker, Michael Lewis's 1989 memoir, an ironic antibildungsroman in which the hero is fascinated but ultimately repelled by life at Salomon Brothers, popularized life on Wall Street for a generation of college students. As Lewis wrote much later,

> I hoped that some bright kid at, say, Ohio State University who really wanted to be an oceanographer would read my book, spurn the offer from Morgan Stanley, and set out to sea.
>
> Somehow that message failed to come across. Six months after *Liar's Poker* was published, I was knee-deep in letters from students at Ohio State who wanted to know if I had any other secrets to share about Wall Street. They'd read my

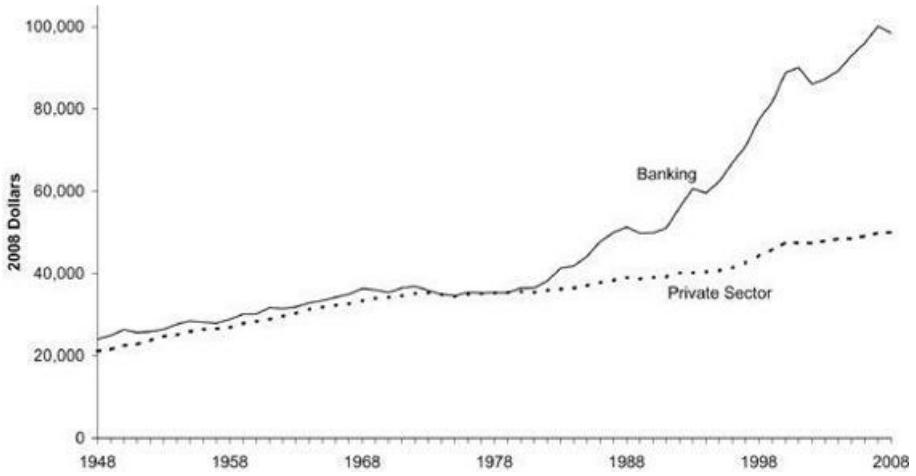
book as a how-to manual.[74]

Clearly, being a bond trader on Wall Street was different from being a loan officer in the era of 3–6–3 banking. The risk, the testosterone, and the sums of money at stake were all deeply seductive to overachievers from top schools. They *wanted* to order guacamole in five-gallon drums, swear constantly, and place million-dollar bets while eating cheeseburgers.

After *Liar's Poker,* the financial sector only became more and more exciting in popular culture. From Salomon, the torch of innovation passed to Drexel Burnham Lambert and Michael Milken, who were starring characters in James Stewart's 1992 bestseller, *Den of Thieves;* the takeover binge they made possible was memorialized by Bryan Burrough and John Helyar in *Barbarians at the Gate,* their 1990 account of the leveraged buyout of RJR Nabisco. After Drexel collapsed, the cutting edge of finance shifted to derivatives desks. In his 1997 memoir, *F.I.A.S.C.O.,* former derivatives trader (and current law school professor) Frank Partnoy chronicled the derivatives culture, where people would describe a trade where they made money at the expense of a client as "ripping his face off." (The comparatively genteel phrase in *Liar's Poker* was "blowing up a customer.") But if Partnoy expected his book to slow the growth of the derivatives industry, he was no doubt disappointed. By this point, the bankers were the heroes of the story, not the villains.

No amount of cautionary tales could change the fact that Wall Street was becoming a deeply seductive place, in a way that traditional banking never was. There were the concrete-steel-and-glass towers crammed full of modern technology. There was the mathematical complexity of modern trading, a game seemingly reserved for the very smart. There was the feeling of being at the center of the financial world, whether raising billions of dollars for multinational corporations or making massive trades that moved the market prices flashing on the Bloomberg screen. There was the lifestyle—eating sushi at Nobu, riding everywhere in a Lincoln Town Car, talking on cell phones (before everyone had one), checking e-mail on BlackBerrys (before everyone had one), and globetrotting in first class (still not available to everyone). To open *Sex and the City,* the 1996 book that launched the eponymous TV show, Candace Bushnell chose an investment banker: "Tim was forty-two, an investment banker who made about $5 million a year."[75]

Figure 4-1: Real Average Annual Compensation, Banking vs. Private Sector Overall



Source: Bureau of Economic Analysis, *National Income and Product Accounts*, Tables 1.1.4, 6.3, 6.5; calculation by the authors. Banking includes financial sector less insurance, real estate, and holding companies. Annual compensation is total wage and salary accruals divided by full-time equivalent employees.

And, of course, there was the money. The vast amounts of money flowing through Wall Street and the extreme free market ethos of the industry resulted in ever-larger amounts of money spinning off into the bank accounts of top traders, salesmen, and bankers. From 1948 until 1979, average compensation in the banking sector was essentially the same as in the private sector overall; then it shot upward, as shown in Figure 4-1, until in 2007 the average bank employee earned twice as much as the average private sector worker.[76] Even after taking high levels of education into account, finance still paid more than other professions. Thomas Philippon and Ariell Reshef have analyzed financial sector compensation and found that the "excess relative wage" in finance—the amount that cannot be explained by differences in education level and job security—grew from zero around 1980 to over 40 percentage points earlier this decade; 30–50 percent of excess wages in finance cannot be explained by differences in individual ability. They also found that deregulation was one factor behind the recent growth of compensation in finance. (Figure 4-2 shows the relationship between the unadjusted relative wage in the financial sector—the ratio between average wages in finance and average wages in the private sector as a whole—and the extent of financial

deregulation, as calculated by Philippon and Reshef.)[77]

The rewards for success grew much, much faster as traders' potential bonuses climbed into the millions and then the tens of millions. In 2008—which was a horribly bad year for most banks—1,626 JPMorgan Chase employees received bonuses of more than $1 million; at the smaller Goldman Sachs, which had thirty thousand employees, 953 received bonuses of more than $1 million, and 212 received bonuses of more than $3 million.[78] In the 1990s, Internet start-ups were seen as the quickest route to vast wealth, for the lucky few who founded companies that successfully went public. By the 2000s, it was investment banks and hedge funds, where smart college graduates could *expect* to make millions.

Wall Street began to skim off the cream of America's top schools— not only graduates of business schools and Ph.D. programs in math and science, but twenty-two-year-old college students with no background or expertise in anything at all. As investment banks began descending onto Ivy League campuses and tempting students with stories of client "impact," dinners at expensive restaurants, and glimpses of much greater wealth, seniors who had never even wondered what a bond was suddenly wanted to be investment bankers. Sealing the deal was the fact that Wall Street was perceived as the ultimate door-opener, a respectable way to make money and then, like Robert Rubin, go into public service. The point of the "Greed is good" speech was that by pursuing profits (both for your company and for yourself) you were contributing to the greater good. For college seniors, it was easy to think that maximizing their personal earnings coincided with maximizing societal good—making it easy to justify joining the ranks of the bankers on Wall Street.

As a result, banking and finance became more and more popular among the young and the privileged. Claudia Goldin and Lawrence Katz have examined data on Harvard undergraduates and found that while only 5 percent of men in classes around 1970 were in finance fifteen years after graduation, that figure tripled to 15 percent for classes around 1990.[79] The share of each class entering banking and finance careers grew from under 4 percent in the 1960s to 23 percent in recent years.[80] At Princeton's School of Engineering and Applied Science, "Operations Research and Financial Engineering" became the most popular undergraduate major.[81] The banks thus became major beneficiaries of the American educational system. Whether society benefited is another question. Kevin Murphy, Andrei Shleifer, and Robert Vishny have argued that society benefits more when talented people become entrepreneurs who start companies and create real innovations than when they go into rent-seeking activities that redistribute rather than increase wealth.[82] If this is true, then this diversion of talent to Wall Street constituted a real tax on economic growth over the last two decades.

Among the economic and intellectual elites, finance became a highly prestigious and desirable profession. Working on Wall Street became a widely acknowledged marker for educational pedigree, intelligence, ambition, and wealth. Outsiders may not have understood exactly what happened on a trading floor or in a hedge fund, but they knew that it was important, it was fast-moving, it was intellectually complicated, it had something to do with greasing the wheels of the global economy, and it had something to do with making it easier for ordinary people to buy houses. They also knew that it was very well paid. In America, where we like to believe that wealth is a function of hard work and contribution to society, that was all good.

THE WALL STREET–TREASURY COMPLEX

This combination of money, people, and prestige created what Jagdish Bhagwati identified in 1998 as the "Wall Street–Treasury complex."[83] Bhagwati described how the ideology of free markets "lulled many economists and policymakers into complacency about the pitfalls that certain markets inherently pose," while the revolving door placed representatives of Wall Street into influential positions in Washington. "This powerful network," he wrote, "is unable to look much beyond the interest of Wall Street, which it equates with the good of the world." Bhagwati was writing in the context of global financial liberalization, which the United States was then pushing on developing countries (both directly and through its influence at the IMF), and which had contributed to the emerging market crises of the past year.

By the time of Bhagwati's article, the power of Wall Street reached deep into Washington. The major banks, including both traditional investment banks and commercial banks that expanded into securities and derivatives, had spent the last two decades opening and exploiting vast new mines filled with money. They had funneled millions of dollars of that money to key congressmen who could make or break legislation affecting the financial sector. The treasury secretary was a former chairman of Goldman Sachs, the assistant secretary for financial markets was a former Goldman partner, and the Federal Reserve chairman was an ardent fan of Wall Street. The Clinton administration, which had tied its fortunes to keeping Wall Street bond traders happy, was deep into a multiyear campaign to boost homeownership rates and was depending on the financial sector to make it possible.

Behind these Washington power brokers was a new conventional wisdom about the importance and value of Wall Street. The previous Nobel Prize in economics had been given to two economists who had helped launch the derivatives revolution and were now partners at the hottest hedge fund in the world. The dogma of financial innovation had few doubters in Washington. Vibrant, profitable banks were assuming the status of national champions in a country that saw the transition from manufacturing to knowledge-intensive services as its destiny. And Wall Street was the most prestigious destination for graduates of America's top universities. For all intents and purposes, Wall Street had taken over.

* A put option gives its holder the right to sell an asset, such as a share of stock, at a predetermined price. If the stock falls sharply in value, the put option allows the holder to sell it at a higher-than-market price, and is therefore a form of protection against risk. The "Greenspan put" was thought to be the equivalent of a put option for everyone in the market.

* Owning a house has other advantages, such as increased freedom in deciding what to do with the house and land and increased peace of mind. However, these advantages have nothing to do with the value of the house as an investment.

THE BEST DEAL EVER

> These amendments are intended to reduce regulatory costs for broker-dealers by allowing very highly capitalized firms that have developed robust internal risk management practices to use those risk management practices, such as mathematical risk measurement models, for regulatory purposes.

By the mid-1990s, Wall Street was a dominant force in Washington. It had survived the implosion of the savings and loan industry in the late 1980s, the election of a Democratic president in 1992, a congressional investigation of predatory subprime lending in 1993, and a wave of scandals caused by toxic derivatives deals in 1994 without facing any significant new constraints on its ability to make money.

The U.S. financial elite did not owe its rise to bribes and kickbacks or blood ties to important politicians—the usual sources of power in emerging markets plagued by "crony capitalism." But just as in many emerging markets, it constituted an oligarchy—a group that gained political power because of its economic power. With Washington firmly in its camp, the new financial oligarchy did what oligarchies do—it cashed in its political power for higher and higher profits. Instead of cashing in via preferred access to government funding or contracts, however, the major banks engineered a regulatory climate that allowed them to embark on an orgy of product innovation and risk-taking that would create the largest bubble in modern economic history and generate record-shattering profits for Wall Street.

When the entire system came crashing down in 2007 and 2008, governments around the world were forced to come to its rescue, because their economic fortunes were held hostage by the financial system. The title of Louis Brandeis's 1914 book, *Other People's Money,* referred to ordinary people's bank deposits, which could be used by investment bankers—"Our Financial Oligarchy"—to control industries and generate profits. In 2008, however, the banks found another way to tap other people's money: the taxpayer-funded bailout.

THE GOLDEN GOOSE

The boom in real estate and finance in the 2000s resulted from the explosive combination of a handful of financial "innovations" that were invented or greatly expanded in the 1990s: structured finance, credit default swaps, and subprime lending. Most financial regulators looked on the creation of this new money machine with benevolent indifference. Structured financial products were sold largely to "sophisticated" investors such as hedge funds and university endowments and therefore subject to limited oversight by the Securities and Exchange Commission; credit default swaps were insulated by regulatory inattention and then by the Commodity Futures Modernization Act; subprime lending was winked at by the Federal Reserve. That was how the financial sector wanted it, and Washington was happy to oblige.

Traditionally, investors invested in financial assets that had some direct tie to the real economy: stocks, corporate or government bonds, currencies, gold, and so on. By contrast, banks engineer structured products to have any set of properties (maturity, yield, risk, and so forth) that they want.[2] Structured products include pure derivatives, discussed in chapter 3, which are side bets on other financial assets. For example, an investor can pay $100 to a bank and get back, one year later, an amount that is calculated based on the performance of several currencies and interest rates. They can also be built by buying actual financial assets (mortgages, student loans, credit card receivables, and so on), combining them, and taking them apart in various ways to create new "asset-backed" securities. Or they can combine real assets with derivatives in increasingly complicated mixes.

Structured finance, in principle, serves two main purposes. First, it creates new assets that people can invest in. Instead of being limited to publicly traded stocks and bonds, investors can choose from a much broader menu of assets, each with unique characteristics to attract a particular investor; for example, securities can be manufactured to help investors match the timing of their assets and their liabilities.* Second, by creating assets that are more attractive to investors, structured finance should make it easier for businesses to raise money. While investors might demand a high rate of interest to invest in an airline route from Los Angeles to Shanghai, they might accept a lower rate if that route were packaged with an option to buy oil at a cheap price in the future. (If oil prices rise, hurting demand for long-distance flights, the option will increase in value.) Lower rates make it easier for businesses to raise money.

In theory, then, structured finance could increase the pie for everyone. More important, in practice it was sure to increase revenues for the banks arranging these complex transactions. The ordinary trajectory for most products and services in the business world is for profit margins to decline as competition increases. For example, the amount that a bank could make from a plain-vanilla loan to a highly rated company was minimal, because many other banks would be willing to make that loan. Like all businesses, banks needed to invent new products that were not yet commoditized and that could command high margins. Structured products were the perfect answer. They were complex products that bank customers could not arrange on their own. Moreover, because selling these products required the ability to hedge risks in multiple markets, it was difficult for new banks to break into the business, which became dominated by a small number of players who could charge hefty fees for their services. In his memoir, former trader Frank Partnoy described how Morgan Stanley earned $75 million on a single trade.[3]

In addition to pure derivatives such as interest rate swaps, currency swaps, and credit default swaps, asset-backed structured products were a mainstay of Wall Street derivatives desks in the early 1990s. The Repackaged Asset Vehicles that played a starring role for Morgan Stanley were structured products, in which a special-purpose vehicle (SPV, a new company that exists only on paper) bought a set of existing securities (say, bonds issued by the state electric utility of the Philippines) and paid for them by selling investors a new set of custom-designed securities.[4]

Asset-backed structured products became Wall Street's new cash cows, in the form of mortgage-backed securities (MBS) and their cousins, collateralized debt obligations (CDOs). The original mortgagebacked securities created by Ginnie Mae in the late 1960s were "pass-through" securities: mortgages were combined in a pool, and each security had an equal claim on the mortgage payments from that pool, spreading the risk evenly. Private MBS, however, are typically divided into different tranches, or classes, that have different levels of risk and pay different interest rates. Because the "senior" tranches have the first claim on all the mortgage payments, they have the least risk, and the credit rating agencies routinely stamped them with their AAA rating—the same rating given to U.S. government bonds. The "junior" tranches are riskier, but therefore pay higher interest rates to investors.*

A CDO is similar, except that instead of being built out of whole mortgages it is built out of mortgage-backed securities or securities backed by other assets (such as credit card loans, auto loans, or student loans).† By building CDOs out of junior, high-yielding MBS tranches, banks were able to engineer new securities that offered high returns with relatively little risk—at least according to their models. It was possible to combine low-rated MBS tranches, mix them together, and create a new CDO, 60 percent or even 80 percent of which was rated AAA; even though the MBS (the inputs) had low ratings, it was

unlikely that many of them would default at the same time—at least according to the models. Financial engineers even created CDO-squareds—CDOs whose raw material was other CDOs—and higher-order variants, in order to squeeze out higher yield at lower supposed risk.[5]

In the late 1990s, Wall Street became addicted to mortgage-backed securities and CDOs. As housing prices took off, it became easy to build models showing that MBS and CDOs had virtually no risk, because borrowers could always refinance their mortgages as long as prices were rising; even if they defaulted, rising prices meant that the investors would own valuable collateral. But because borrowers—especially subprime borrowers—were individually risky and paid interest rates to match, it was possible to manufacture AAA-rated securities that paid higher interest rates than other low-risk assets, such as U.S. Treasury bonds. Comforted by their AAA ratings, investors bought those CDOs without worrying about what was inside them. Most important, U.S. homeowners and homebuyers represented an enormous pool of potential borrowers that could be tapped over and over again as home prices rose and as they bought bigger houses or refinanced to turn their home equity into cash for home improvements or flat-screen televisions. Those mortgages and home equity loans were the raw material that Wall Street transformed into gleaming new CDOs for investors, taking a flat fee with each turn of the assembly line.

In comparison with MBS and CDOs, credit default swaps (insurance against default), introduced in chapter 3, are a relatively simple product, but they played a special role in the finance boom. Because the boom was based on creating, packaging, and selling debt, it depended on the assumption that borrowers would pay off their debts—or that someone else would pay in their place. Credit default swaps made it possible to insure *any* pool of mortgage loans or mortgage-backed securities, seemingly eliminating the risk of default.

In 1997, J.P. Morgan (part of today's JPMorgan Chase) pioneered the use of credit default swaps to shift the default risk of loans off of its balance sheet. In the "BISTRO" transaction, J.P. Morgan's derivatives team created a new special-purpose vehicle to insure loans the bank had made. J.P. Morgan paid insurance premiums to the SPV, and the premiums backed new bonds issued by the SPV to investors.[6] This complex piece of engineering had two benefits for the bank. First, because the risk of default on the underlying loans had been transferred from the bank to the SPV, the bank did not have to maintain capital reserves for those loans, so it could make more loans and hence more lending profits.

The other implication was more far-reaching. In effect, J.P. Morgan had created a new CDO out of thin air, without any of the raw material—loans or asset-backed securities—usually required. BISTRO was the first of what came to be known as "synthetic CDOs." If the borrowers paid off their loans, the SPV would receive a steady stream of insurance premiums from J.P. Morgan to pay off its investors; but if the borrowers defaulted, the SPV would have to make a large cash insurance payout to J.P. Morgan, and its investors would lose their money. From an economic standpoint, it was as if the SPV actually held the underlying loans. This meant that a bank could create a CDO based on the housing market without having to buy a pool of mortgages or mortgage-backed securities; instead, it only needed to find someone who would buy insurance (using credit default swaps) on securities that already existed in the market. No one, in other words, had to go to the trouble of lending new money.

In the 2000s, as demand from investors and Wall Street banks for subprime loans outstripped supply, credit default swaps were used to fill the gap. As hedge fund manager Steve Eisman said, "They weren't satisfied getting lots of unqualified borrowers to borrow money to buy a house they couldn't afford. They were creating them out of whole cloth."[7] This practice ultimately magnified the impact of mortgage defaults; as borrowers stopped paying, their defaults hurt not only the CDOs that held bits and pieces of their mortgages, but also the synthetic CDOs that mirrored them.

Credit default swaps also made possible another Wall Street business model. With a stable economy and rising housing prices, the default risk of the senior tranches of mortgage-backed securities and CDOs (the ones that got paid off first) seemed vanishingly small. Selling credit default swaps on these securities looked an awful lot like free money, and hedge funds stepped forward to take it. Notably, American International Group (AIG), the world's largest insurance company, had a Financial Products group that was willing to insure AAA-rated structured securities for almost nothing. In the late 1990s, AIG agreed to insure the "super-senior" portion of J.P. Morgan's CDOs—the part that was even safer than the AAA-rated bonds issued by the SPV[8]—for only two basis points (hundredths of a percentage point) per year. In other words, in return for insuring $100 million of loans against default, AIG would get $20,000 per year.[9] According to AIG's models, it was free money. From J.P. Morgan's perspective, because AIG was considered one of the world's safest companies—it had a AAA rating of its own at the time—it was fully insured, for a cheap price. Everyone was happy. Of course, risk never disappears, and in this case it would reappear with a vengeance in September 2008.

The third ingredient of this money machine was a wave of innovation in mortgages, often described as (but not confined to) subprime lending. Traditionally, since the 1930s, home mortgages had been relatively conventional products and mortgage lending a relatively staid business. Most mortgages were long-term, fixed-rate, "prime" mortgages, where the borrower met the

lender's standards for creditworthiness, capacity (income) to repay debt, and collateral (real property sufficient to protect the lender in case of default).[10] Subprime loans, where the borrower did not meet one of these criteria,* were relatively rare. In 1993, there were only 24,000 subprime mortgages used to purchase homes and 80,000 subprime refinance mortgages. By contrast, there were 2.2 million prime home purchase mortgages and 5.2 million prime refinance mortgages; in aggregate, there were seventy prime mortgages for every subprime mortgage.[12]

The 1990s and 2000s, however, saw an explosion in all types of mortgage lending, although most attention has focused on subprime lending (and "Alt-A," a new designation for higher-end subprime loans), in which lenders lowered their standards for creditworthiness, capacity, or collateral, or all three at the same time. Before the market for private mortgage-backed securities took off in the 1990s, subprime lending was constrained by the fact that subprime lenders wanted to be paid back. Subprime loans had to conform to underwriting standards, like all loans, and were used primarily to refinance prime mortgages for borrowers who had poor credit histories but otherwise had the capacity to repay the debt. In addition, subprime loans were generally made by nonbank mortgage lenders who could not raise funds by taking deposits from customers. With the advent of securitization, however, investors and the investment banks that served them became particularly hungry for subprime loans because of the higher interest rates they paid, which were crucial to manufacturing high-yielding CDOs.

Now that loans could be resold to Wall Street, mortgage lending became a fee-driven business, where volume was the key to profits. Lenders responded by inventing new mortgage products that made it easier for borrowers to afford their monthly payments, at least for the first few years. These products went beyond the standard adjustable rate mortgage to extreme forms such as "pay option" mortgages where borrowers could choose to pay *less* than the monthly interest on the loan, causing the principal balance to go up instead of down. Lenders relaxed traditional underwriting practices, such as verifying the income and assets of the borrower; in stated-income mortgages, the lender explicitly *did not* confirm that the borrower had the income he or she claimed, and told the borrower as much. They accepted smaller down payments, resulting in higher loan-to-value (LTV) ratios, or used second mortgages to eliminate the down payment entirely; this meant that the collateral would not be sufficient to protect the lender from default unless housing prices rose.[13]

Many of these innovations applied equally to prime and subprime loans, and business in both categories boomed. In 2005, 1.0 million subprime loans were used to buy houses and 1.2 million were used for refinancing—in aggregate, a twenty-fold increase over 1993.[14] The result—whether due to mortgage brokers who pushed borrowers into inappropriate loans, or due to house "flippers" who took on as much leverage as possible to buy as many houses as possible while the market was hot—was mortgages that many borrowers would have little chance of actually paying off out of their income.

But that no longer mattered—at least not to the lenders or the investment banks—because the lending business model detached itself from the requirement that borrowers pay back their loans. Lenders made fees for originating loans; the higher the interest rate, the higher the fees. Then, when interest rates reset and borrowers became unable to make their monthly payments, lenders could earn more fees by refinancing them into new, even-higher-rate mortgages. As long as housing prices continued to rise, a single borrower could be good for multiple loans, each time increasing his debt. (This business model had been pioneered by credit card issuers, who discovered that they could make money off of borrowers even if they never fully paid off their card balances.)[15] If he finally became unable to refinance, any loss would typically be taken by a CDO investor, not by the mortgage lender, and would be confined to the junior CDO tranches. As late as 2007, according to the International Monetary Fund, "Stress tests conducted by investment banks show that, even under scenarios of nationwide house price declines that are historically unprecedented, most investors with exposure to subprime mortgages through securitized structures will not face losses." (The stress test cited by the IMF was conducted by Lehman Brothers.)[16]

As the business boomed, the large banks dived in, snapping up subprime lenders. Among the top twenty-five subprime lenders, First Franklin was bought by National City and later by Merrill Lynch; Long Beach Mortgage was bought by Washington Mutual; Household Finance was bought by HSBC; BNC Mortgage was bought by Lehman Brothers; Advanta was bought by JPMorgan Chase; Associates First Capital was bought by Citigroup; Encore Credit was bought by Bear Stearns; and American General Finance was bought by AIG.[17] Not only did buyers want the lucrative fees available from originating subprime loans, but many of them wanted a captive source of loans for their mortgage securitization machines. Large banks also expanded their subprime operations by working with independent mortgage lenders and brokers. According to the head of Quick Loan Funding, a subprime lender, Citigroup provided the money for loans to borrowers with credit scores below 450 (at the time, the national median was about 720).[18] JPMorgan Chase aggressively marketed its "no doc" and "stated-income" programs to mortgage brokers and used slogans such as "It's like money falling from the sky!"[19] If subprime lending was pioneered far from Wall Street, by the 2000s Wall Street couldn't get enough of it.

Housing was not the only bubble made possible by cheap money, aggressive risk-taking, and structured finance. The 2000s saw a parallel bubble in the commercial real estate market, where banks were willing to finance purchases at ever-increasing valuations, in part because they were able to use commercial mortgage-backed securities to unload the large, risky loans they were making. There was also an enormous boom in takeovers of companies by private equity firms, again made possible by cheap loans advanced by banks and then syndicated to groups of investors or used as raw material for new structured products.

These bubbles overlapped in takeovers of real estate investment trusts (REITs), companies that invest in real estate. In February 2007, the Blackstone Group bought Equity Office Properties Trust for $39 billion in the largest leveraged buyout ever; Blackstone immediately flipped most of Equity Office's buildings to other buyers (who borrowed as much as 90 percent of the purchase price), many of whom took significant losses as the real estate market crashed.[20] In October 2007, Tishman Speyer spent $22 billion to buy Archstone-Smith Trust, much of it financed by a group of banks led by Lehman Brothers; losses on that deal would be one factor that helped lead to the downfall of Lehman less than a year later.[21]

But the emblematic bubble of the decade, and the one whose implosion led directly to the financial crisis, was the housing bubble, in which prices soared to almost twice their long-term average (see Figure 5-1).[22] The increased availability of mortgage loans, with lower initial monthly payments, increased homebuyers' ability to pay, pushing prices upward. Continually rising housing prices seemed to eliminate the risk of default, since borrowers could always refinance when their mortgages became unaffordable, making mortgage-backed securities and CDOs more attractive to investors and to the investment banks that manufactured them. Higher prices also induced existing homeowners to take out home equity loans, providing more raw material for asset-backed securities and CDOs. Lower risk lowered the price of credit default swaps on mortgage-backed debt, making CDOs and synthetic CDOs easier to create. Increased Wall Street demand for mortgages (to feed the securitization pipeline) funneled cheap money to mortgage lenders, who sent their sales forces out onto the streets in search of more borrowers; by the early 2000s, many prime borrowers had already refinanced to take advantage of low rates, and so subprime lending became a larger and larger share of the market. And the cycle continued.

Ordinarily, the instinct for financial self-preservation should prevent lenders from making too many risky loans. The magic of securitization relieved lenders of this risk, however, leaving them free to originate as many new mortgages as they could. Because mortgages were divided up among a large array of investors, neither the mortgage lender nor the investment bank managing the securitization retained the risk of default. That risk was transferred to investors, many of whom lacked the information and the analytical skills necessary to understand what they were buying. And the investors assumed that they didn't need to worry about what they were buying, because it was blessed by the credit rating agencies' AAA rating.

Ironically, even though securitization theoretically allowed banks to pass on all the default risk to their clients, some kept some of the risk anyway. Either they really believed that the senior tranches of their CDOs were risk-free, or there was more demand for the riskier junior tranches and they couldn't find enough buyers for the senior tranches. Here again, they depended on financial innovation in the form of structured investment vehicles (SIVs)—special-purpose entities that raise money by issuing commercial paper and invest it in longer-term, higher-yielding assets. Citigroup, for example, used SIVs to buy over $80 billion in assets by July 2007.[23] These vehicles allowed banks to invest in their own structured securities without having to hold capital against them; since SIVs were technically not part of the bank in question—even though they were wholly owned by that bank, which might even have promised to bail them out if necessary[24]—their assets were not counted when determining capital requirements. The result was that SIVs enabled banks to take on more risks with the same amount of capital.

SIVs were a Wall Street variation on one form of crony capitalism. In an emerging market, when a major family-owned conglomerate sets up a new company, it can legally walk away should things go bad. Because the new company has the family name behind it, however, the family will come under pressure to prop it up in a crisis.[25] And just as in emerging markets, when things did go bad in 2007 and 2008, many banks, including Citigroup, bailed out their SIVs, incurring billions of dollars of losses in the process. But as long as housing prices were soaring, SIVs were another way to make more profits using less

capital. In addition, by soaking up the senior tranches of CDOs, they helped keep the securitization machine going at full volume.

Rising housing prices created their own momentum, as bubbles do. As people saw their friends and neighbors cashing in on the housing boom, they rushed to get in on the action. The environment became so filled with stories about people making money in housing that even skeptics decided that everyone else couldn't be wrong, creating what Robert Shiller has called a "rational bubble."[26] Even investors who knew the boom could not last were betting that they could buy high and sell higher before the music stopped.

On a factory farm, when hens start laying fewer eggs, they are "force-molted"—"starved of food and water and light for several days in order to stimulate a final bout of egg laying before their life's work is done."[27] After 2004, when many qualified borrowers had already refinanced and houses were so expensive they could only be bought with exotic mortgages, the real estate and finance industries launched an all-out effort to get people into new houses and squeeze out a few last years of golden eggs. In the peak years, the bubble was sustained by brand-new mortgage products that only existed because they provided raw material for CDOs. At the height of the boom, over half of the mortgages made by Lennar, a national housing developer, were interest-only mortgages or optional-payment mortgages whose principal went *up* each month; in 2006, almost one in three had a piggyback second mortgage.[28] Between 1998 and 2005, the number of subprime loans tripled, and the number that were securitized (as measured by First American LoanPerformance) increased by 600 percent.[29] In 2005, a consortium of Wall Street banks created standard contracts for credit derivatives based on subprime mortgages, making it even easier to create synthetic subprime CDOs.[30] These developments all confirmed the predictions of economist Hyman Minsky, who had warned that "speculative finance" would eventually turn into "Ponzi finance."[31]

The end result was a gigantic housing bubble propped up by a mountain of debt—debt that could not be repaid if housing prices started to fall, since many borrowers could not make their payments out of their ordinary income. Before the crisis hit, however, the mortgage lenders and Wall Street banks fed off a giant moneymaking machine in which mortgages were originated by mortgage brokers and passed along an assembly line through lenders, investment banks, and CDOs to investors, with each intermediate entity taking out fees along the way and no one thinking he bore any of the risk.[32]

GREENSPAN TRIUMPHANT

An emerging market oligarchy uses its political power and connections to make money through such means as buying national assets at below-market prices, getting cheap loans from state-controlled banks, or selling products to the government at inflated prices. In the United States, the banking oligarchy (and its allies in the real estate industry) used its political power to protect its golden goose from interference and to clear away any remaining obstacles to its growth. The banks' objectives included both the elimination or nonenforcement of existing regulations and the prevention of new regulations that might stifle profitable innovations. Their sweeping success enabled them to take on more and more risk, increasing their profits but also increasing the potential cost of an eventual crash.

At the top of the major commercial banks' wish list was the repeal of the Glass-Steagall Act, which was finally achieved in 1999. By that point, the separation of commercial and investment banking had been severely weakened by a series of Federal Reserve actions that allowed commercial banks, through their subsidiaries, to underwrite many types of securities; in addition, the new business of derivatives fell outside Glass-Steagall altogether, and commercial banks such as Bankers Trust and J.P. Morgan were among the pioneers in that market.

In 1996, the Fed struck a major blow for deregulation, allowing bank subsidiaries to earn up to 25 percent of their revenues from securities operations, up from 10 percent.[33] That same year, the Fed overhauled its regulations to make it easier for banks to gain approval to expand into new activities. Congress also changed the rules for banks seeking to expand into new businesses, relieving banks of the need to obtain approval from the Federal Reserve and putting the onus on the Fed to actively disapprove of any new activities.[34] As long as Glass-Steagall remained on the books, however, the 25 percent revenue limit posed a barrier, and there was still the risk that Congress or the courts might overrule a friendly decision by the Fed.

When Travelers and Citicorp merged in 1998—bringing together a major commercial bank and a major insurance company that owned a major investment bank—Glass-Steagall required the new Citigroup to break itself up within two years. Citigroup's only recourse was to get the law repealed. Congress obliged in 1999 with the Gramm-Leach-Bliley Act, which created a new category of financial holding companies that are authorized to engage in any activities that are financial in nature, incidental to a financial activity, or complementary to a financial activity—including banking, insurance, and securities.[35] With this legislation, Donald Regan's dream of a true financial supermarket that could offer all financial services was not only legal, it seemed to be embodied in the new Citigroup.

The passage of Gramm-Leach-Bliley freed not only Citigroup but also Bank of America, J.P. Morgan, Chase, First Union, Wells Fargo, and the other commercial megabanks created by the ongoing merger wave to plunge headlong into the business of buying, securitizing, selling, and trading mortgages and mortgage-backed securities. Because there was no way to seal off the banks' securities operations from their ordinary banking operations, this meant that the government guarantee of the banking system, in place since the 1930s, was effectively extended to investment banking. Deposits that were insured by the Federal Deposit Insurance Corporation could be invested in risky assets, with the assurance that losses would be made up by the FDIC. The larger the bank, the stronger its government guarantee. In 1984, when Continental Illinois was bailed out, the comptroller of the currency said that the top eleven banks were too big to fail; by 2001, there were twenty banks that were as big relative to the economy as the eleventh-largest bank had been in 1984.[36] As in any capitalist system, bank employees and shareholders would enjoy the profits from their increasingly risky activities; but now the federal government was on the hook for potential losses.

A major test of Wall Street's power was regulation of derivatives. Because they did not directly involve either deposits or traditional securities, and because they defied conventional treatment on an accounting balance sheet, customized derivatives posed a new challenge to the existing regulatory framework. The first threat to this new profit center arose in 1994 because of the major derivatives losses suffered by Orange County, Procter & Gamble, and Gibson Greetings, among others.

In response, Congress took up the issue of derivatives regulation. The House Banking and Financial Services Committee conducted a major investigation, and several bills to regulate derivatives were proposed. The industry countered with a major lobbying effort coordinated by the International Swaps and Derivatives Association (ISDA), which was received sympathetically by Alan Greenspan and by the Wall Street–friendly Clinton administration. Treasury Undersecretary Frank Newman urged Congress not to regulate derivatives;[37] Treasury Secretary Lloyd Bentsen also backed the industry, saying, "Derivatives are perfectly legitimate tools to manage risk. Derivatives are not a dirty word. We need to be careful about interfering in markets in too heavy-handed a way."[38]

The Group of Thirty, an international advocacy group largely composed of private sector bank executives, central bankers, and sympathetic academics, chimed in with a study concluding that no new regulation was required and that the industry could

be trusted to regulate itself.[39] The study was overseen by Dennis Weatherstone, then chair of J.P. Morgan. *The New York Times* reported at the time, "Many of those people conducting the study work at businesses that have a stake in assuring the market's continued prosperity. They were trying to head off calls for greater regulation and supervision by addressing these concerns."[40] And they were entirely successful. By the end of 1994, the lobbying effort had killed off all congressional efforts at regulation. Some customers who had been burned by derivatives were able to win settlements from their derivatives brokers, but these isolated cases did little to stem the growth of the industry.[41]

This was only one of several high-profile battles over regulation in the last two decades (but perhaps the only one that Wall Street had any chance of losing). Another struggle was precipitated by Brooksley Born's campaign as chair of the Commodity Futures Trading Commission (CFTC) to *think about* regulating over-the-counter derivatives. Born was concerned that the buildup of large derivatives positions invisible to regulatory oversight could create risks for the financial system as a whole.[42] She was opposed not only by Greenspan, Rubin, and Summers, but also by Securities and Exchange Commission chair Arthur Levitt and House Banking Committee chair Jim Leach. On May 7, 1998, the same day that Born's "concept release" was published, Rubin, Greenspan, and Levitt went public with their "grave concerns … about reports that the CFTC's action may increase the legal uncertainty concerning certain types of OTC derivatives."[43] In June, they proposed draft legislation imposing a moratorium on regulatory action by Born's agency.

In July 1998, before the House Banking Committee, representatives from Treasury, the SEC, and the major banking regulators lined up with Greenspan and executives from several major banks to oppose Born and testify that derivatives markets were functioning effectively without additional regulation. Greenspan said, "professional counterparties to privately negotiated contracts also have demonstrated their ability to protect themselves from losses, from fraud, and counterparty insolvencies"; he concluded, "aside from safety and soundness regulation of derivative dealers under the banking or securities laws, regulation of derivatives transactions that are privately negotiated by professionals is unnecessary. Regulation that serves no useful purpose hinders the efficiency of markets to enlarge standards of living."[44] In October, the moratorium was approved. The next year, Born decided not to seek reappointment.

From the perspective of the derivatives industry, however, winning the battle was not enough. Not satisfied that derivatives were unregulated, the industry used its influence to ensure that derivatives would never be regulated. In November 1999, the President's Working Group on Financial Markets produced a report, "Over-the-Counter Derivatives Markets and the Commodity Exchange Act," signed by Summers (then treasury secretary), Greenspan, Levitt, and new CFTC chair William Rainer. That report concluded that, in order "to promote innovation, competition, efficiency, and transparency in OTC derivatives markets, to reduce systemic risk, and to allow the United States to maintain leadership in these rapidly developing markets," those derivatives should be exempted from federal regulation.[45]

The financial sector's supporters in Congress complied by passing the Commodity Futures Modernization Act (CFMA), introduced in May 2000 but held up in the Senate due to Senator Phil Gramm's desire for even stricter deregulatory language.[46] Ultimately, Gramm succeeded in foreclosing any possibility of regulation by the CFTC or the SEC; in the middle of December, the bill was inserted into the Consolidated Appropriations Act for Fiscal Year 2001, passed by a lame-duck Congress, and signed by a lame-duck president. The financial sector had succeeded in sealing off one of its profit-making engines from the possibility of government interference.

Another key goal of the Wall Street banks was to maximize their leverage, and structured finance was a key to their strategy. Leverage is an easy way to increase profits. If you invest $10 of your money at a 10 percent return, you will gain $1 in profits; but if you invest $10 of your money and $90 of borrowed money at a 10 percent return, your profits will be $10. Conversely, however, leverage increases the chances that you will be wiped out; a 10 percent loss on $10 of your own money is only $1, but a 10 percent loss on $10 of your money and $90 of borrowed money leaves you with nothing.

This is why regulators place limits on the amount of leverage a bank can take on, in the form of minimum capital requirements. Capital is the amount of money put up by the bank's owners (shareholders), and acts as a safety cushion in times of stress; the more capital, the more money the bank can lose before it becomes unable to return money to its depositors and repay its debts. Capital requirements are set as a percentage of the bank's assets. For every $100 in assets, a bank might have to hold $10 in capital, which means it can borrow only up to $90; this is the same as saying its leverage cannot be more than nine to one. Therefore, to maximize profits per dollar invested (capital), banks want to maximize their leverage; put another way, for the same assets, they want to hold as little capital as possible.

One motivation for securitization was to exploit a loophole in existing regulatory capital requirements. The amount of capital a bank had to hold depended on the type of assets it held; in theory, the riskier the asset, the more capital was required. The loophole was that these requirements were set somewhat arbitrarily—4 percent for home mortgages, 8 percent for unsecured commercial loans, and so on. As a result, a bank could take $100 of assets that required, say, $8 in capital; put them into a securitization pool; and, through the magic of structured finance, convert them into $100 of new securities that were

treated differently by capital regulations and therefore required only $5 in capital. The true risk of the assets hadn't changed, since the probability of default hadn't changed. But because financial engineers could create securities with just the right characteristics needed to get just the right credit ratings, they could control the amount of capital that was required. So a bank could use securitization to *keep* the economic risk of its loans while reducing its capital requirements (so it could go and make more loans).

In addition to securitization, credit default swaps could be used to reduce capital requirements and increase leverage. The same J.P. Morgan team that pioneered the synthetic CDO also first lobbied federal regulators for permission to use credit default swaps to reduce their capital requirements. In 1996, the Federal Reserve Board of Governors obliged.[47] With both securitization and credit default swaps in their arsenal, Wall Street's financial engineers could concoct increasingly elaborate mechanisms for repackaging risk in ways that reduced its regulatory footprint.

Federal regulators were well aware of these practices. In 2000, for example, Federal Reserve economist David Jones published a paper with detailed examples of how banks could engage in regulatory capital arbitrage (RCA). "[R]egulatory capital standards seem destined to become increasingly distorted by financial innovation and improved methods of RCA," he wrote, "at least for those large, sophisticated banks having the resources to exploit such opportunities." Jones argued that this could actually be a good thing: "Against the backdrop of regulatory capital requirements that are often quite arbitrary, in some circumstances RCA actually may improve a bank's financial condition and the overall efficiency of the financial system. Indeed, RCA is widely perceived as a 'safety valve' for mitigating the adverse effects of regulatory capital requirements."[48]

Instead of attempting to crack down on banks' attempts to get around minimal capital requirements, federal regulators went in the other direction and loosened those requirements. In 2001, the federal bank regulators issued a new rule standardizing the capital requirements for securitizations.[49] If the bank creating the securitization retained some of the risk of the assets involved (which it often did in order to attract investors), the new rule calculated the bank's capital requirements based on ratings set by credit rating agencies (or, in some cases, the banks' own internal models). The goal of this rule was to align capital requirements with the degree of economic risk taken on by the bank, which was supposedly measured by the rating agencies. Instead, however, it meant that banks could get away with anything, so long as they could convince a rating agency to approve it.[50]

Not surprisingly, "shopping for ratings" became a standard part of securitizations. Banks would tweak their models until they got the ratings that they needed in order to sell some of the tranches to investors and keep some tranches for themselves. Rating agencies—who were being paid by the banks to rate these securities—complied, granting AAA ratings to thousands of securities at a time when only a handful of companies enjoyed AAA ratings for their bonds.*[51] According to Jim Finkel of Dynamic Credit, which created structured products, "Wall Street said, 'Hey, if you don't [give me the rating I want], the guy across the street will. And we'll get them all the business.' And they just played the rating agencies off one another." One investment banker who worked on these securitizations said, "It makes me feel really bad actually, it's very hard for me to acknowledge.… I knew I was doing things to get around the rules. I wasn't proud of it but I did it anyway."[52] The rating agencies were hardly passive victims. A McClatchy investigation found that even as the housing market was starting to crumble, Moody's was forcing out executives who questioned the agency's high ratings of structured products and filling its compliance department with people who had specialized in giving those ratings.[53]

By making capital requirements dependent on credit ratings, the regulators put this critical aspect of oversight in the hands of a small number of rating agencies that themselves depended on the banks for their revenues. With limited competition and little ability for investors to understand the rating process, the agencies had little incentive to give accurate ratings; by contrast, they had a lot of incentive to keep their key clients—the investment banks—happy. In 2004 and 2005, some rating agencies modified their rating models in ways that made it easier to give higher ratings to CDOs, helping extend the structured finance boom. But when the bubble finally burst, they ended up downgrading over 75 percent of asset-backed CDOs that had gotten AAA ratings in 2006 and 2007.[54]

Regulators went even further and outsourced control over minimum capital requirements to the banks they were regulating. On April 28, 2004, the Securities and Exchange Commission agreed to a request by the five large investment banks—Goldman Sachs, Morgan Stanley, Merrill Lynch, Lehman Brothers, and Bear Stearns—to use their own internal models, based on historical data, to calculate the "net capital" in their broker-dealer operations. The rule was explicitly intended to reduce the regulatory burden on the major investment banks by increasing their net capital, thereby enabling them to expand their business:

> These amendments are intended to reduce regulatory costs for broker-dealers by allowing very highly capitalized firms that have developed robust internal risk management practices to use those risk management practices, such as mathematical risk measurement models, for regulatory purposes. A broker-dealer's deductions for market and credit risk probably will be lower under the alternative method of computing net capital than under the standard net capital rule.[55]

Between 2003 and 2007, all five major investment banks increased their overall leverage, taking on larger and riskier

positions that increased their expected profits while increasing their overall risk.[56] Bear Stearns's leverage reached a ratio of thirty-three to one, meaning that if its assets fell by 3 percent the bank would be insolvent; it was the first to fall in 2008 when *rumors* that it might be insolvent caused its short-term funding to dry up in a matter of days.

In exchange for being allowed to increase their leverage, the investment banks gave the SEC new powers to monitor their operations through the Consolidated Supervised Entity program. However, the SEC declined to take effective action under this program. A 2008 investigation by the SEC inspector general found that

> [the SEC's Division of Trading and Markets] became aware of numerous potential red flags prior to Bear Stearns' collapse, regarding its concentration of mortgage securities, high leverage, shortcomings of risk management in mortgage-backed securities and lack of compliance with the spirit of certain Basel II standards, but did not take actions to limit these risk factors.[57]

By this point, many regulators had bought into the idea that the financial markets could police themselves, so there was no need to intervene.

Securitization, credit default swaps, and more flexible capital requirements all made it possible for banks to increase their leverage, increasing both profits and risks. Historically, regulators have set limits on leverage, because it increases the likelihood of failures that may require government intervention. In the past twenty years, Wall Street banks invented new ways of getting around those limits. More important, the regulators no longer felt the need to protect the financial system by defending those limits, instead acquiescing in the general belief that markets were best left to police themselves.

Another potential threat to Wall Street's golden goose was regulation of mortgage lending, and subprime lending in particular. The mortgage lenders were not unaware of this danger. Between 2000 and 2007, the lenders that lobbied most intensively against potential legislation restricting predatory lending were precisely those lenders who originated the riskiest mortgages (measured by loan-to-income ratios), grew the fastest, and grew the proportion of mortgages that they securitized the fastest.[58] (They were also hit the hardest by the eventual financial crisis.) But the industry was fortunate to be protected by powerful figures in Washington.

In 1994, back when subprime lending was off Wall Street's radar, Congress had passed the Home Ownership and Equity Protection Act, which amended the Truth in Lending Act to read, "A creditor shall not engage in a pattern or practice of extending credit to consumers under [high-cost refinance mortgages] based on the consumers' collateral without regard to the consumers' repayment ability, including the consumers' current and expected income, current obligations and employment."[59] In other words, it banned predatory lending—loans where the lender doesn't care if the borrower can't make his or her payments, because then the lender can pick up the house cheaply. However, under the arcane structure of financial regulation, consumer protection statutes including the Truth in Lending Act were enforced by the Federal Reserve—headed throughout this entire period by Alan Greenspan, who not only opposed government regulation in general, but thought that even fraud would be deterred by the operation of a free market.

The Federal Reserve sidestepped its consumer protection responsibilities by claiming it lacked jurisdiction. Many subprime loans—52 percent of those originated in 2005, for example[60]—were made not by banks, but by nonbank consumer finance companies or mortgage lenders. By the late 1990s, however, many of these specialized lenders had been bought up by banks (through their holding companies) or had been started by banks as independent subsidiaries. Consumer groups amassed mounting evidence of abusive lending practices, particularly in low-income and minority communities, and pressed the Fed to investigate. In 1998, however, the Federal Reserve Board of Governors unanimously decided "to not conduct consumer compliance examinations of, nor to investigate consumer complaints regarding, nonbank subsidiaries of bank holding companies,"[61] claiming it could not regulate nonbank entities[62] (even though the Truth in Lending Act makes no distinction between banks and nonbanks).[63]

In 2000, a joint report issued by Treasury (then under Larry Summers) and the Department of Housing and Urban Development recommended restrictions on harmful sales practices and on abusive terms and conditions in the mortgage market.[64] The report also urged the Fed to investigate abusive lending practices, claiming it had authority to do so.[65] That same year, Edward Gramlich, a member of the Board of Governors, argued that the Fed should crack down on predatory lending by consumer finance lenders that were subsidiaries of bank holding companies. His proposal, like all the others, was shot down by Greenspan, who believed that subprime lending was an example of healthy financial innovation.[66] (Conforming to the usual practice of not airing disagreements among governors, Gramlich did not go public with his concerns while at the Fed. Shortly before he died in 2007, however, he wrote, "In the subprime market, where we badly need supervision, a majority of loans are made with very little supervision. It is like a city with a murder law, but no cops on the beat.")[67] As late as 2005, Greenspan was still celebrating the growth in subprime lending:

> Where once more-marginal applicants would simply have been denied credit, lenders are now able to quite efficiently judge the risk posed by individual applicants and to price that risk appropriately. These improvements have led to rapid growth in subprime mortgage lending; indeed, today subprime mortgages account for roughly 10 percent of the number of all mortgages outstanding, up from just 1 or 2 percent in the early 1990s.[68]

While the Federal Reserve was neglecting to protect consumers, other regulatory agencies were neglecting to ensure the soundness of the banks they supervised. At the peak of the subprime lending boom, the Office of Thrift Supervision (OTS) was allowing thrifts to *reduce* their capital levels, which fell to their lowest level in decades by 2006. Only in 2005 did the Office of the Comptroller of the Currency (OCC) initiate a proposal saying that lenders should have to make sure that borrowers could afford their monthly payments; even then, it was not actually issued until September 2006, by which point housing prices were already falling.[69] Material loss reviews conducted after many smaller banks had failed in 2009 showed that banking regulators were often aware of the risks that the banks were running, but failed to take any significant corrective action.[70]

While federal regulators were content to turn a blind eye to subprime lending—when they were not cheering it on—there remained the risk that state regulators might attempt to put an end to the party. In 1999, the North Carolina Predatory Lending Law subjected high-cost (subprime) loans to a number of constraints, such as limits on loan flipping (refinancing a borrower into a new loan after only a few years) and prepayment penalties; in 2002, the Georgia Fair Lending Act introduced similar restrictions.[71] Standard & Poor's responded by announcing that it would not allow any loans governed by the Georgia Fair Lending Act into securitizations that it rated; if similar laws had been enacted throughout the country, this would have brought the subprime mortgage securitization assembly line to a screeching halt.[72]

However, the primary federal bank regulators came to the industry's aid, ruling that state regulations are "preempted" by federal regulations.* In August 2003, the OCC ruled that state regulation of lending practices did not apply to national banks, preempting the Georgia Fair Lending Act and holding that federal regulators alone had the power to regulate lending activities by federally chartered institutions.[73] This decision followed letters by the chief counsel of the OTS concluding that federal law preempted both the Georgia Fair Lending Act and the New Jersey Home Ownership Security Act of 2002.[74] (Later in 2003, the OCC also preempted the New Jersey law; in January 2004, it exempted national banks from state mortgage regulations in general.)[75] The federal courts have usually sided with federal regulatory agencies on the issue of preemption, giving the OCC and the OTS the ultimate say on whether states may regulate banking operations.[76] During the subprime boom, the effect was to disarm state governments and give the mortgage lenders (and the investment banks securitizing their loans) free rein throughout the fifty states.

In addition to protecting the flow of subprime loans into the securitization market, the federal government also increased demand for subprime loans through its regulation of Fannie Mae and Freddie Mac. The financial crisis was not primarily due to Fannie and Freddie.[77] However, their purchases of securities that were backed by subprime loans did, at the margin, provide additional sales for the Wall Street banks manufacturing those securities.

Before 2008, Fannie Mae and Freddie Mac were governmentsponsored enterprises (GSEs)—private corporations with a government mandate to provide liquidity to the housing market. They did this by buying mortgages and mortgage-backed securities on the secondary market and by creating and guaranteeing mortgage-backed securities of their own. To protect themselves, they only bought loans or guaranteed mortgage-backed securities made out of loans that conformed to their relatively strict (by industry standards) underwriting standards and size limits—so-called conforming loans. (The upper limit on conforming loans for single-family houses grew from about $253,000 in 2000 to $417,000 in 2006, but still left many houses beyond its reach.)[78] Because Fannie and Freddie could borrow money cheaply, there was a ready supply of cash that could flow into mortgage lending.

The common indictment of Fannie and Freddie charges that Democrats in Congress, trying to expand homeownership among the poor and minorities, pushed the GSEs to buy more and more subprime loans, pumping up subprime lending and housing prices in the process. (The implication, of course, is that the financial crisis was caused by government intervention in the markets.) There is a grain of truth to this story. The targets set by HUD in both the Clinton and George W. Bush administrations (under a law passed in 1992) mandated that 42 percent, 50 percent, and finally 56 percent of the loans bought by Fannie and Freddie had to go to people with low or moderate incomes. In 2002, as part of the Bush administration's Blueprint for the American Dream, they committed to finance $1.1 trillion in loans to minority borrowers.[79]

The riskiest mortgages, however—the ones that pushed the housing bubble to dizzying heights—were simply off-limits to Fannie and Freddie. The GSEs could not buy many subprime mortgages (or securitize them) because they did not meet the conforming mortgage standards. As profit-maximizing private corporations, Fannie and Freddie tried to relax their underwriting standards in order to get into the party, reducing documentation requirements and lowering credit standards. But ultimately, regulatory constraints prevented them from plunging too far into subprime lending. As housing expert Doris Dungey

wrote, "[T]he immovable objects of the conforming loan limits and the charter limitation of taking only loans with a maximum [loan-to-value ratio] of 80% … plus all their other regulatory strictures, managed fairly well against the irresistible force of 'innovation.' "[80]

As a result, in 2004–2006, as subprime lending reached its peak in both volume and innovation, Fannie and Freddie were pushed out of large parts of the market, because the loans being made violated their underwriting standards and because the Wall Street banks were so eager to get their hands on those loans. After 2003, the GSEs' share of secondary market subprime loans was cut in half, while the volume of private mortgage-backed securities (those not issued by the GSEs) soared.[81] Fannie and Freddie could not have pushed mortgage lenders into the most extreme forms of subprime lending, because those were precisely the loans they could not buy. They created demand for conforming mortgages, which were precisely what the aggressive subprime lenders were *not* selling.

Instead, however, Fannie and Freddie were able to buy the senior (AAA-rated) tranches of private mortgage-backed securities backed by subprime debt. These securities could count as money loaned to people with below-average income, and they were supposed to be safe.[82] These purchases of MBS were a mechanism by which government pressure to increase lending to low-income Americans translated into greater demand for mortgage-backed securities and therefore greater profits for Wall Street. At the end of the day, government pressure on Fannie and Freddie contributed to the housing bubble by increasing the amount of money flowing into the securitization pipeline. The two GSEs were not the primary factor stoking the subprime fire, and were consistently behind the curve as both subprime lending and securitization heated up, out-hustled by the mortgage lenders and the Wall Street banks who built, expanded, and profited from the mortgage securitization money machine. But they were yet another way that Washington provided fuel for that machine.

Finally, the Federal Reserve hooked its massive air pump to the housing bubble by keeping interest rates historically low from 2001 well into 2005. The federal funds rate (the rate at which banks borrow money from each other overnight) stood at 6.5 percent for most of 2000, before a recession and the terrorist attacks of September 11, 2001, prompted the Fed to cut it to 1.75 percent by the end of 2001.* It fell as low as 1.0 percent in 2003 and only began climbing again in June 2004, by which point real housing prices were 58 percent above their levels of January 2000. The federal funds rate didn't reach 3.0 percent—the *lowest* level of the entire 1990s—until May 2005, when real housing prices were 77 percent above their levels at the beginning of the decade.[83]

Cheap money was important because low mortgage rates were a central ingredient in the housing and securitization boom. Low rates made it easier for people to afford larger mortgages, pushing up housing prices. Low rates also induced existing homeowners to refinance their mortgages, providing more raw material for the securitization pipeline. At any point in the decade, a sharp increase in interest rates could have punctured the housing bubble by making houses less affordable and forcing prices down. But the Federal Reserve, true to the conclusion of Greenspan's 1996 "irrational exuberance" speech—that the Fed should not attempt to identify bubbles but should simply clean up afterward—declined to act.

The irony is that the Fed's flood of cheap money did not even have the healthy effect that it should have had. Ordinarily, businesses should take advantage of low interest rates to make capital investments, which contribute to overall economic growth. In the 2000s, however, as Tim Duy notes, business investment in equipment and software grew more *slowly* than in the 1990s, despite the lower interest rates. The problem was that the cheap money was misallocated to the housing sector, resulting in anemic growth.[84] That misallocation was due to the new mortgage products that made it so easy to borrow large amounts of money, the voracious appetite of Wall Street banks and investors for securities backed by those mortgages, and a decade of government policies that encouraged the flow of money into housing. And the more money that flowed into new subdivisions in the desert, the less flowed into new factories where Americans could go to work. Ultimately, the price of the housing bubble and the financial crisis is not just trillions of dollars of losses on mortgages and mortgage-backed securities, but a decade of poor economic growth and declining real household incomes.*

Even before the financial crisis of 2007–2009, politicians and officials in Washington had opportunities to witness the potential consequences of financial innovation run riot. But they drew the wrong lessons each time, allowing the banks to take more risks and make more money. The derivatives scandals of 1994 had cost clients hundreds of millions or billions of dollars, but posed no real danger to the financial system as a whole. The same could not be said of the near collapse of Long-Term Capital Management in 1998, which led to its bailout by a group of New York banks (facilitated by the Federal Reserve Bank of New York).[86]

The LTCM bailout was the right move for the Fed to make in the short term. It protected the financial system without putting public money directly at risk. However, the successful rescue sent the message that the Fed would not let private market actors suffer the consequences of their own bad decisions; while the LTCM partners lost most of their money, the banks that had blindly lent money to the fund lost none of theirs. It is impossible to say just what effect the rescue had on the behavior of Wall

Street over the next decade. But it is clear that LTCM, with its $130 billion in debts and seven thousand open derivatives positions with a face value of $1.4 trillion,[87] was considered "too big to fail"—words that would become infamous almost exactly ten years later.

In addition, the ability of the Fed to avert disaster—and even to keep the stock market rising by cutting interest rates in September, October, and November 1998—undermined any incentive to do anything about the root causes of the LTCM near disaster. If this was the worst damage that unregulated financial institutions trading unregulated products could do, then perhaps regulation was unnecessary. Congress apparently agreed; it was in October 1998, only a month after LTCM had been saved, that it imposed the moratorium preventing the CFTC from regulating custom derivatives.

The collapses of Enron, WorldCom, and other high-flying companies in 2001–2002 also should have made clear that free markets did not deter fraud on their own. WorldCom committed straightforward accounting fraud that was missed by its auditors, the banks underwriting its new debt, and the credit rating agencies rating that debt.[88] Enron used special-purpose entities, derivatives, disguised loans, and aggressive accounting to shift revenues forward and backward in time, create phantom profits, and hide debts; while its intentions seemed to be fraudulent, the financial techniques it used were so novel that it was not clear which were illegal and which were merely innovative.[89] Some of its financial engineering techniques would reemerge in the financial crisis of 2007–2009, as would the banks it used—a class-action lawsuit named JPMorgan Chase, Citigroup, Credit Suisse First Boston, CIBC, Bank of America, Merrill Lynch, Barclays, Deutsche Bank, and Lehman Brothers as its enablers.[90]

Enron and WorldCom showed both the consequences of hyperactive financial innovation and the failure of "self-regulation" by the free market. Enron's creditors, who should have been lending money carefully, instead were helping it create fake transactions.[91] The credit rating agencies failed to disentangle Enron's web of special-purpose entities and maintained its investment-grade rating until well after the company's problems were front-page news. Old-fashioned regulation was also missing in action. In the wake of the Enron collapse, the Senate Governmental Affairs Committee concluded, "The Securities and Exchange Commission largely left the search for fraud to private auditors and boards of directors."[92]

Confronted with this wake-up call, Congress and the Bush administration limited themselves to bolting the particular barn door exploited by the Enron-WorldCom generation. The Sarbanes-Oxley Act of 2002 established new standards for corporate financial statements (and, by 2007, was under widespread attack from the business community for being too stringent). It did not occur to anyone in power that some of the ingredients that made Enron possible—financial innovations dreamed up by Wall Street banks hungry for large transaction fees, off-balance-sheet accounting, weak credit rating agencies, credulous investors, a largely fawning media, and ineffectual federal regulators—might already be recombining in a different form.

The SEC—the nation's chief regulator of the securities markets and investment banks—stepped up enforcement briefly after Enron, but enforcement actions declined again during the chairmanship of Christopher Cox from 2005 to 2009. Under Cox, the five-member commission that governed the agency often delayed action on opening investigations, delayed approval of settlements, or reduced penalties recommended by enforcement officials, resulting in an 84 percent decline in penalties.[93] Instead of focusing on enforcement, powerful commissioners such as Paul Atkins argued that the SEC should pare back regulations that were seen as imposing excessive costs on the free market.[94]

The SEC also failed to exercise its powers to oversee the securities industry. In the wake of the collapse of Bear Stearns, the SEC inspector general found that the agency not only took no meaningful action under the Consolidated Supervised Entity program, but also did a poor job implementing its Broker-Dealer Risk Assessment program (created in 1992 in response to the failure of Drexel Burnham Lambert). Under that program, the SEC received quarterly and annual reports from 146 broker-dealers—but generally only reviewed six of them.[95] Most famously, the SEC managed to overlook Bernie Madoff's $65 billion Ponzi scheme, despite tips and investigations going back to 1992.[96]

This failure to regulate the securities markets effectively was a consequence of the deregulatory ideology introduced by Ronald Reagan as well as the political influence of Wall Street. James Coffman, a former assistant director of the SEC's enforcement division, wrote,

> Elected deregulators appointed their own kind to head regulatory agencies and they, in turn, removed career regulators from management positions and replaced them with appointees who had worked in or represented the regulated industries. These new managers and, in many cases, the people they recruited and promoted, advanced or adhered to a regulatory scheme that, at least with respect to the most important issues, advanced the interests of the regulated.[97]

After all, the industry's mantra was that financial markets could self-regulate, so there was no need for the government. Once the government accepted this logic, it unilaterally disarmed in a sweeping abdication of its responsibility to the people it

served.

THE GOLDMAN SACHS SAFETY NET

As much as the Wall Street banks wanted Washington's hands off their moneymaking businesses, they still had no stomach for doing business without the protection of the U.S. government. This attitude is consistent with the history of the business-government relationship in the United States. While occasional libertarian academics and politicians have favored deregulation in its pure form, real companies see regulatory or deregulatory policies simply as a way to improve their market position or profit-making potential. And one benefit Wall Street banks wanted was the security of knowing that the government's effectively unlimited balance sheet and borrowing power would be there for them should they need it.

Did bank executives consciously take excessive risks because they expected taxpayers to cushion their potential losses? This is not something that a Wall Street CEO is likely to admit, and it is possible that on an individual level they simply underestimated the risks involved and expected their winning streaks to continue indefinitely. But the government safety net was on at least some bankers' minds. Andrew Haldane, executive director for financial stability at the Bank of England, has told the story of a meeting (prior to the recent crisis) where government officials asked private-sector bankers why they did not conduct rigorous "stress tests" of their own portfolios; the answer, according to one participant, was that in the event of a severe shock, "the authorities would have to step in anyway to save a bank and others suffering a similar plight."[98] In any case, the behavior of major financial institutions made sense largely because of implicit government guarantees. Increasing leverage, increasing the proportion of assets held for trading purposes, buying riskier assets, and selling out-of-the-money options (such as credit default swaps) are all strategies that increase returns in good times but increase losses in bad times; therefore, they make the most sense for banks that can shift those higher losses onto someone else. (Ordinarily, banks' creditors would prevent them from pursuing these risky strategies, because their money would be on the line; if creditors expect to be bailed out by the government, however, there is no need for them to monitor the banks closely.) And they are all strategies that were pursued during the recent boom by major global financial institutions, including those in the United States.[99]

We do know that executives of at least one major bank thought about the government safety net. Since 1932, Section 13 of the Federal Reserve Act had given the Fed the power, in "unusual and exigent circumstances," to make loans to anyone—but only if the collateral provided in exchange arose "out of actual commercial transactions."[100] This requirement specifically excluded investment securities, which meant that in a crisis, investment banks might not have any valid collateral with which to borrow from the Fed.

This danger worried the remarkably prescient executives at Goldman Sachs. At their suggestion, the "actual commercial transactions" requirement was dropped in a "miscellaneous provision" of the Federal Deposit Insurance Corporation Improvement Act of 1991, ensuring that the Fed could lend against *any* collateral in a time of crisis.[101] This change gave the Fed the power to widen its protective umbrella to encompass investment banks, at the same time that those banks were increasing the riskiness of their operations by expanding their derivatives and proprietary trading businesses and taking on additional leverage. This seemingly minor change would be of crucial importance seventeen years later; when the housing bubble of the 2000s ended—and with it the seemingly unlimited supply of money flowing from novel and largely unregulated financial products—not only investment banks but a major insurance company would have to be rescued with government money.

* For example, pension funds with long-term liabilities should prefer to invest in long-term assets, so they are getting their money back at the same time that they need to make payouts.

* In a stylized example, an MBS offering might be composed of 85 percent senior MBS and 15 percent junior MBS. If 5 percent of the underlying mortgages default, the junior investors will lose one-third of their money, but the senior investors will lose nothing. The senior investors only lose if over 15 percent of the underlying mortgages default. By contrast, in a pass-through MBS, there are no tranches; if 5 percent of the mortgages default, all investors lose 5 percent of their money.

† There is not universal agreement on terminology. A mortgage-backed security with tranches is sometimes called a CDO. A CDO backed by mortgage-backed securities is sometimes classified as a mortgage-backed security (because ultimately it, too, is backed by mortgages).

* Contrary to popular belief, not all subprime loans are loans to poor people. The classification of a loan depends on the relationship between the borrower, the property, and the size of the loan. Chris Mayer and Karen Pence have found that "subprime mortgages are not only concentrated in the inner cities, where lower-income households are more prevalent, but also on the outskirts of metropolitan areas where new construction was more prominent."[11]

* In 2005, only eight U.S. companies had AAA bond ratings: AIG, Automatic Data Processing, Berkshire Hathaway, ExxonMobil, General Electric, Johnson & Johnson, Pfizer, and United Parcel Service.

* Preemption is a legal doctrine holding that certain areas regulated by the federal government may not be regulated by

the states—even if they wish to enact more stringent requirements than those prescribed by federal regulators.

* The Federal Reserve controls the federal funds rate by buying and selling Treasury securities, which decreases or increases the amount of money available to banks, thereby affecting the rate at which banks lend to each other. The federal funds rate has an important though indirect influence on all interest rates in the economy.

* Average real annual growth has been lower in the 2000s (through 2008) than in any decade since the 1930s; real median household income (in 2008 dollars) has fallen from $52,587 in 1999 to $50,303 in 2008.[85]

TOO BIG TO FAIL

> To paraphrase a great wartime leader, never in the field of financial endeavour has so much money been owed by so few to so many. And, one might add, so far with little real reform.
>
> —Mervyn King, governor of the Bank of England, October 20, 2009[1]

On October 13, 2008, their stock prices in tatters and the short-term viability of their firms in doubt, the heads of nine major banks—Bank of America, Bank of New York Mellon, Citigroup, Goldman Sachs, JPMorgan Chase, Merrill Lynch, Morgan Stanley, State Street, and Wells Fargo—arrived at the Treasury Department for a meeting with Treasury Secretary Henry Paulson.* Each was given a term sheet agreeing to sell shares to the government, and Paulson told them to sign it.[2]

This might seem like a government takeover of the financial sector—a seizure of ownership interests in nine major banks. And given the stakes—a near-total freeze of credit markets, a plunge in the stock market, the potential collapse of those and yet more banks—that would not have seemed too far-fetched. But the remarkable thing about this meeting was not that the government was stepping in to protect the U.S. financial system and, by extension, the global economy. What was remarkable was something that Vikram Pandit, CEO of Citigroup, noticed instantly: "This is very cheap capital!"[3] It was such a good deal that John Mack, CEO of Morgan Stanley, signed the term sheet immediately, even before consulting his board of directors.[4]

Few people at the time were arguing that the government should sit on its hands and let the financial sector implode. But few also expected Paulson, Federal Reserve chair Ben Bernanke, and Federal Reserve Bank of New York president Tim Geithner to rescue the banks on such generous terms. The October 13 deal was structured as a purchase of preferred shares, which effectively meant that Treasury loaned the banks money, at an initial 5 percent annual interest rate (a rate that was not available in the market), that never had to be repaid.[5] (Treasury also received options to buy a small amount of common shares at a predetermined price.) The purchases theoretically meant that the government now owned part of the banks, but Treasury promised that it would not influence the management of the banks and would not vote for members of their boards of directors.* It was close to free money.

Why was this such a sweet deal? Although banks borrow most of their money, all banks need capital—money that cannot be demanded back by creditors. Capital serves as a buffer that prevents a bank from failing when its assets fall in value. In good times, when capital is readily available, banks prefer to borrow as much as possible in order to maximize their profits, keeping their capital levels low; but in bad times like October 2008, when banks most need additional capital, it is at its most expensive—because who wants to invest in a bank that may fail the next day?

But as Pandit recognized, the government was giving the banks capital cheaply; Warren Buffett, by contrast, had just invested in Goldman Sachs at a 10 percent interest rate. (Buffett also received more options than Treasury, and at a bigger discount to the then current market price.) In short, Paulson, a former CEO of Goldman Sachs, was pushing free money at his former colleagues. Phillip Swagel, then a Treasury assistant secretary, later wrote, "This had to be the opposite of the 'Sopranos'—not a threat to intimidate banks but instead a deal so attractive that banks would be unwise to refuse it."[6] According to Swagel, the government had to offer attractive terms because it could not force the banks to agree to any investment, and it is true that some bankers claimed that they did not need government capital.[7] However, the government did have considerable negotiating leverage, thanks to its regulatory authority, its ability to threaten *not* to bail out banks later should they need it, and the fact that banks would be taking a risk by walking away without money that their competitors had. And the government officials involved fully appreciated the strength of their position. During the meeting, Paulson responded to an objection by saying, "Your regulator is sitting right there," referring to the director of the Office of the Comptroller of the Currency and the chair of the Federal Deposit Insurance Corporation. "And you're going to get a call tomorrow telling you you're undercapitalized and that you won't be able to raise money in the private markets."[8]

The government's largesse was not limited to capital at a bargain basement rate. At the October 13 meeting, officials also revealed that the government would begin guaranteeing debt issued by the banks, allowing them to raise money by selling bonds to private investors who now knew that the government would protect their investments. Together, these two measures constituted an extraordinary gift from the government, on behalf of taxpayers, to the financial sector.

At the time—with Lehman Brothers bankrupt, Bear Stearns and Merrill Lynch sold, and Goldman Sachs and Morgan Stanley fleeing for the safety of bank holding company status (which gave them increased access to emergency lending from the Federal Reserve)—many observers thought the financial crisis signaled the demise of Wall Street. For the onetime "masters of the universe," being forced to accept government money was a humbling blow. And even with the cushion of a large government subsidy, the banks seemed unlikely to return to the high-flying ways of the boom. America's leading business newspaper put its

name on a book entitled *The Wall Street Journal Guide to the End of Wall Street as We Know It.* [9] An era, it seemed, was ending.

Today, however, it is clear that Wall Street did not end. While some fabled institutions have vanished, the survivors have emerged larger, more profitable, and even more powerful. The vague expectation that the government would bail out major financial institutions when necessary has become official policy. The connections between Wall Street and Washington have become stronger. A Democratic administration has done everything in its power to restore a private, profitable financial sector. A casual observer would be forgiven for thinking that Washington has behaved like an emerging market government in the 1990s—using public resources to protect a handful of large banks with strong political connections. Whether this was due to political capture or to unbiased economic policymaking, the result was the same: Wall Street only became stronger as a result of the financial crisis.

The story of the financial crisis of 2007–2009 has been told many times.[10] Policymakers, economists, and commentators have pointed to many causes and contributing factors, ranging from "oversaving" in China to basic human psychology.[11] However, few would deny that a U.S. financial system that inflated an asset bubble with cheap lending, manufactured colossal amounts of complex and potentially toxic securities, levered up with debt to maximize profits, and binged on short-term funding played a central role in bringing on the crisis. Even under the theory (popular among Americans) that a glut of saving in China created a flood of cheap money in the United States, leading to overborrowing and the housing bubble, that money had to flow through the American financial system, which did a phenomenally poor job of allocating it efficiently.

This system was made possible by the rise of the financial sector over the past three decades. Members of the Washington establishment bought into Wall Street's vision of free-flowing capital and unfettered innovation. Whether they were true believers or cynics out to maximize their campaign contributions or their future earning potential, policymakers helped the major banks by relaxing regulations, declining to enforce existing regulations, or neglecting to regulate new markets. This is why mortgage originators were allowed to make loans that got bigger over time, making them harder to pay off; why those mortgages could be packaged into securities that masked their intrinsic risk; why banks could stash those securities in off-balance-sheet vehicles and pretend they didn't own them; why they could use fancy risk models that said that nothing could go wrong with those securities; why trillions of dollars of side bets could be placed on those same securities; and ultimately why trillions of dollars of assets ended up precariously perched on top of a bubble of debt.

In 2006, the air began leaking out of that bubble, housing prices began to fall, and borrowers unable to refinance their mortgages started defaulting in sharply rising numbers. In 2007, the mountain of assets based on housing values began to crumble as increasing defaults torpedoed the prices of mortgage-backed securities and collateralized debt obligations (CDOs). In 2008, the resulting avalanche almost brought down the global financial system. Key government policymakers made admirable efforts to save the financial system. But the actions they took ultimately demonstrated the importance of a particular worldview in Washington—the idea that big, risk-loving banks are crucial to our economy and our way of life.

ON THE EDGE OF THE CLIFF

The financial crisis played out in a series of increasingly frightening episodes on Wall Street. Each scare prompted concern in Washington. But the three men who dominated economic policy through the end of the Bush administration—Paulson, Bernanke, and Geithner—hoped to avoid direct government intervention, preferring the approach of cushioning the downturn through increased liquidity and lower interest rates. Only in 2008 did they recognize that they were dealing with the kind of collapsing debt bubble common to emerging market crises in the 1990s—a scenario that required stronger measures.

Problems became widely visible in summer 2007, when Bear Stearns and then BNP Paribas revealed problems with internal hedge funds that had invested heavily in subprime mortgages. The disclosures made investors wonder how many other funds might contain ticking time bombs. The Federal Reserve responded with additional liquidity, lowering the discount rate and the federal funds rate* in an attempt to encourage lending and head off a credit contraction.

Fear only grew, however, as investors next became concerned about the structured investment vehicles (SIVs) that many banks had spawned in order to profit from structured securities while minimizing their capital requirements. As rumors spread that SIVs would either go bankrupt or infect the balance sheets of their sponsoring banks, the government attempted to engineer a backroom deal involving money from private banks. The theory was that the SIVs only faced a short-term liquidity crisis—given time, their assets would recover their value—and therefore deep-pocketed banks could buy them out safely. In October 2007, at the urging of the Treasury Department, several major banks announced a Master Liquidity Enhancement Conduit (MLEC) that would buy several hundred billion dollars' worth of securities from troubled SIVs. However, the idea was quietly dropped in December. Most likely the banks realized that using their own money to bail out their own SIVs—or, as some suspected, pooling the money of many banks to bail out Citigroup's SIVs—did not represent a real solution.

The failure of the MLEC implied that the major banks might be facing more than a simple liquidity crisis and might need more capital. At this point, sovereign wealth funds (investment funds owned by other countries) were still willing to supply that capital. Between October 2007 and January 2008, CITIC (China) committed to invest in Bear Stearns, the Abu Dhabi Investment Authority and the Government of Singapore Investment Group invested in Citigroup, China Investment Corporation invested in Morgan Stanley, and Temasek (Singapore), the Korean Investment Corporation, and the Kuwait Investment Authority invested in Merrill Lynch.[12] But the next time banks needed capital, it would be much harder to find.

The next firestorm erupted in March 2008 with the collapse of Bear Stearns, then considered the weakest of the big five stand-alone investment banks. Bear Stearns was brought down by a modern-day bank run.[13] On a proportional basis, it was more exposed to structured mortgage-backed securities than its rivals, and it was also highly dependent on short-term funding—cash that came from very short-term borrowing, much of it overnight.[14] This meant that its creditors could refuse to roll over their loans from one day to the next and demand their money back instead. If that happened, there was no way Bear could pay them back, since many of its assets were illiquid; structured securities can be hard to sell on short notice, and selling them under pressure would cause their prices to collapse. If some creditors thought that this might happen, they would try to get their money out first, which would provoke other creditors to do the same, triggering a bank run as everyone scrambled to avoid being last in line.

All banks have this potential weakness, since they borrow short and lend long—they borrow money that they promise to return on short notice (deposits), and lend it out for long periods of time (mortgages). The rush by creditors to get their money out first is a classic feature of financial crises around the world, particularly in emerging markets. In the United States since the 1930s, deposit insurance has generally prevented bank runs by depositors—but that insurance did not cover the institutions lending money overnight to Bear Stearns and the hedge funds who parked their securities at Bear.

In early March, rumors surfaced that Bear Stearns was in trouble. Those rumors quickly became self-fulfilling as nervous creditors and hedge fund clients began cutting their exposure to the bank, causing Bear's cash to drain away. Treasury and the Fed faced the prospect that a major investment bank might go bankrupt, tying up its assets in bankruptcy court for months or years and leaving its creditors and counterparties without access to their money. The Fed first attempted to lend Bear money by using JPMorgan Chase as an intermediary (as an investment bank, Bear was not eligible for direct loans from the Fed). When this failed to bolster confidence, Paulson, Bernanke, and Geithner brokered the sale of Bear to JPMorgan for a paltry $2 per share. Even at that price, JPMorgan refused to go along without a government backstop, so the New York Fed agreed to assume all the losses on $30 billion of Bear's illiquid securities.

The deal was soon renegotiated to a purchase price of $10 per share, with JPMorgan now assuming the first $1 billion of losses on the $30 billion pool, which was parked in a special-purpose entity named Maiden Lane.[15] But it remained a coup for JPMorgan, which was paying for Bear Stearns approximately what its *building* was worth[16]—and for its CEO, Jamie Dimon, who happened to be on the board of directors of the New York Fed. The day the acquisition was announced, hoping to prevent the remaining stand-alone investment banks from suffering the same fate as Bear Stearns, the Federal Reserve also announced the creation of the Primary Dealer Credit Facility—a program allowing investment banks for the first time to borrow money

directly from the Fed.[17] This constituted a dramatic expansion in the government's safety net for the banking system.

But the financial epidemic continued to spread as the fall in housing prices accelerated. Because of the complex way in which CDOs and other structured securities had been manufactured, falling housing prices and increasing defaults had a disproportionate impact on the prices of many such securities, which fell in value by 50 percent or more.* For example, in July 2008, Merrill Lynch sold a portfolio of CDOs with a face value of $30.6 billion to Lone Star Funds for only $6.7 billion, or 22 cents on the dollar—and even loaned Lone Star $5 billion to close the deal.[18]

No one knew how many of these toxic assets were sitting on major banks' balance sheets, or how much they would lose if they were forced to sell. Each quarter, banks were taking major write-downs—reducing the accounting value of those assets to reflect their deteriorating quality.† In 2007, Citigroup took $29 billion in write-downs, Merrill Lynch $25 billion, Lehman $13 billion, Bank of America $12 billion, and Morgan Stanley $10 billion.[19] But no one knew if the assets were being written down to their true values, or how long the write-downs would continue. In 2008, Citigroup would take another $63 billion in write-downs, Merrill $39 billion, Bank of America $29 billion, Lehman $14 billion, JPMorgan Chase $10 billion, and Morgan Stanley $10 billion. The suspicion was spreading that if they were forced to acknowledge the true decline in value of their assets, some major banks might turn out to be insolvent.

The next major institutions to come under pressure were Fannie Mae and Freddie Mac, the privately owned but government sponsored enterprises (GSEs) that backed up the housing market. Although Fannie and Freddie had been relatively late to the subprime party, their balance sheets were completely exposed to the housing market, and falling housing prices tore a widening hole in those balance sheets, threatening their survival. This spooked the housing market, which was unlikely to continue functioning without their guarantees. It also frightened foreign governments, China first among them, that had bought hundreds of billions of dollars of bonds from Fannie and Freddie and were counting on the U.S. government to protect them from default.

In July 2008, Paulson asked for and obtained the right to back up Fannie and Freddie with taxpayer money, betting that this alone would stem the panic; "If you've got a bazooka, and people know you've got it, you may not have to take it out," he said at the time.[20] But it was not enough. On September 7, Fannie and Freddie were taken over by the government and placed in a conservatorship—the equivalent of a managed bankruptcy.[21] The government promised to keep the GSEs in operation, and in exchange got a controlling ownership share and the right to manage them. Shareholders lost most of their money and the CEOs were replaced. In effect, the federal government took over two pillars of the financial system because they were too big to fail. Reactions were generally positive, in part because no one wanted to defend the quasi-private, quasi-public status of the GSEs. Other financial institutions had long complained about the unfair advantage that Fannie and Freddie enjoyed because of their government relationship, which made it cheaper for them to borrow money.

In the end, this was the last bailout that everyone could agree on. And it bought Paulson, Bernanke, and Geithner precisely one week.

Until September, most government support had been provided by the Federal Reserve in the form of new lending programs (the guarantee for Bear Stearns's assets was structured as a loan) and lower interest rates. By acting as a lender of last resort, the Fed hoped to engineer a "soft landing" from the boom—the goal its founders sought back in 1913. However, this strategy was about to reach its limits, leaving Paulson, Bernanke, and Geithner with the choice between letting the free market take its course and end in financial and economic disaster, or engineering a massive government intervention in the financial system. The terms of that intervention would reveal the lasting influence and power of the Wall Street ideology—that big, private, lightly regulated financial institutions are good for America.

The precipitating factor was again the collapse of an investment bank—Lehman Brothers, now the smallest of the big four stand-alone investment banks. As with Bear Stearns, rumors emerged that Lehman was short on cash, and those rumors quickly became self-fulfilling. Over the weekend of September 13–14, the government cast about for a buyer. But this time, Paulson and Geithner made clear that they did not want to step in with taxpayer money. Paulson complained, "I'm being called Mr. Bailout. I can't do it again"; more circumspectly, Geithner observed, "There is no political will for a federal bailout."[22] On Saturday night, knowing that no federal money would be available, Jamie Dimon said to his troops at JPMorgan Chase, "We just hit the iceberg. The boat is filling with water, and the music is still playing. There aren't enough lifeboats. Someone is going to die."[23] When a plan for Barclays to acquire Lehman fell through on Sunday, the backup plan was bankruptcy early Monday morning.

Paulson, Bernanke, and Geithner declined to orchestrate a massive rescue that would have required a large loan from the Fed guaranteed by a claim on most of the bank's assets. (The principals have all insisted that they did not have the legal authority to rescue Lehman, because the bank did not have sufficient collateral to support an emergency loan from the Fed—but that argument only appeared weeks later.) They hoped that, since the Bear Stearns emergency in March, financial institutions had prepared themselves for the possibility of Lehman's collapse. As Bernanke said in congressional testimony, "[W]e judged that investors and counterparties had had time to take precautionary measures."[24] Unfortunately, those institutions had learned

the opposite lesson—that the government would *not* let Lehman collapse. As Andrew Ross Sorkin wrote, describing the days before the Lehman bankruptcy, "[M]ost people on Wall Street … assumed that the government would intervene and prevent [Lehman's] failure."[25] The financial sector assumed it could have its cake and eat it too: the government would give it unlimited license to make money in the boom, *and* would shelter it from harm in the bust. But it turned out that the government did not have the resources to protect all of the major banks; this time, the resource in short supply was the political capital necessary to bail out another bank in the face of congressional and public criticism.

The Lehman bankruptcy triggered a chain reaction that ripped through the financial markets. American International Group, which was already struggling with the consequences of its derivatives trades, faced downgrades by all three major credit rating agencies, which would trigger collateral calls that could force it into bankruptcy.* On Tuesday, with the collateral damage caused by Lehman's failure beginning to spread, the Fed stepped in with an $85 billion credit line to keep AIG afloat, fearing that if the insurer defaulted on its hundreds of billions of dollars in credit default swaps, its counterparties would suffer devastating losses—or, at the least, fear of those losses would cause the financial markets to grind to a halt.

Also on Tuesday, the Reserve Primary Fund, one of the largest money market funds, announced that it would "break the buck"; because of losses on Lehman debt, it could not return one dollar for each dollar put in by investors. As a result, money flooded out of money market funds, forcing Treasury to create a new program to provide insurance for those funds. The flight from money market funds dried up demand for the commercial paper used by corporations to manage their cash, raising the specter that major corporations might not be able to make payroll. This forced the Fed to establish a program to buy commercial paper from issuing corporations—in effect lending money not just to banks, but directly to nonfinancial companies.

Banks that relied heavily on short-term funding saw their sources of cash dry up as investors realized that *any* financial institution could fall victim to a bank run. Washington Mutual collapsed as depositors pulled out their money, causing the largest bank failure in U.S. history, and Wachovia, on the brink of failure, was acquired by Wells Fargo. Desperate to hold on to the cash they had, banks stopped lending. Money essentially moved in only one direction, toward U.S. Treasury bills—the presumed safest of all investments—and it stayed there. No one else could get any credit, and without credit the financial system cannot function.

On Thursday, September 18, the financial crisis burst onto the American political stage. Paulson and Bernanke went to Congress asking for $700 billion to buy toxic securities. A controversial three-page summary of their proposal gave the treasury secretary virtually unlimited power to use the money as he saw fit. Congress responded by passing the Emergency Economic Stabilization Act, but not until October 3, after its initial defeat in the House of Representatives triggered a frightening run on the stock market. That bill's central provision, the Troubled Asset Relief Program (TARP), gave Treasury $700 billion to buy "troubled assets" from financial institutions.

In the October 13 meeting at Treasury that opened this chapter, $125 billion of TARP money was committed to nine major banks. In addition to investments in smaller banks, another $40 billion was invested in Citigroup and Bank of America, two of the original nine banks, in later rescue operations; more TARP money was used to finance Federal Reserve guarantees of toxic assets held by those two banks; and $70 billion was invested in AIG to allow it to pay down its credit line from the Fed.[26] In addition, the FDIC promised to insure up to $1.5 trillion of new bank debt, and the Federal Reserve committed trillions of dollars to an ever-expanding list of liquidity programs intended to provide cheap money to the financial system: the Term Auction Facility, the Term Asset-Backed Securities Loan Facility, the Money Market Investor Funding Facility, the Asset-Backed Commercial Paper Money Market Mutual Fund Liquidity Facility, and so on.

Never before has so much taxpayer money been dedicated to save an industry from the consequences of its own mistakes. In the ultimate irony, it went to an industry that had insisted for decades that it had no use for the government and would be better off regulating itself—and it was overseen by a group of policymakers who *agreed* that government should play little role in the financial sector.

OTHER PEOPLE'S MONEY

Although the financial crisis was similar to earlier meltdowns,[27] especially in emerging markets, it was unique in its complexity and scale. A vigorous government response was necessary, particularly after the Lehman bankruptcy. Given the panic that seized financial markets, it was possible that a sudden evaporation of credit, coupled with rapid de-leveraging by financial institutions and corporations everywhere, could have led to a second Great Depression. However, at each point, the government had choices in how it responded to the crisis. To understand the nature of the government response, it is necessary to understand the options that were available.

The core problem was that various financial institutions were in trouble. The immediate threat was a panic-induced bank run, but the underlying issue was that the toxic securities held by banks had plummeted in value. If the banks had to liquidate those assets at current market prices, they would run the risk of becoming insolvent. In short, they needed more cash, or they needed insurance against those assets falling further in value. Broadly speaking, the government's choices lay on a spectrum between two main options.

The first was the "blank check" option. The government, as a source of potentially unlimited money, could keep financial institutions afloat and prevent a systemic collapse by simply giving them the money they needed (by investing new capital, overpaying for banks' assets, or insuring those assets at below-market rates). The second was the "takeover" option. The government could take over failing financial institutions and either clean them up, with the goal of ultimately returning them to private ownership, or shut them down. This is what the FDIC routinely does with smaller banks that become insolvent: it seizes their assets and then operates them in a conservatorship or sells the assets to another bank.

There has been considerable debate over whether the government had the legal authority to take over bank holding companies, as opposed to their commercial banking subsidiaries. While the takeover of holding companies was not anticipated by the regulatory scheme, the government had considerable power to dictate the terms of support to any troubled bank, both because regulators had the power to revoke the license of an insolvent bank and because the government was the only source of financing available to struggling banks.* Thomas Hoenig, president of the Federal Reserve Bank of Kansas City, argued that the government could have placed conditions on any financial support that enabled it to place failing institutions into conservatorship.[28]

Under both the blank check and the takeover scenarios, someone must take the losses. A bank is fundamentally a pile of money that is invested in a set of assets. Some of the money comes from the banks' shareholders and the rest is borrowed from depositors and other creditors. If the assets increase in value, the bank can pay back its depositors and creditors (with interest) and the shareholders keep the gains. If the assets fall in value, the shareholders take the losses, since the bank's debts do not change; if assets continue to fall after the shareholders have lost all their money, depositors (if they are uninsured) and creditors take a "haircut" because the bank cannot pay them back in full.

In the blank check scenario, the government keeps the bank afloat in its current form: managers keep their jobs, shareholders keep some value, and creditors are kept whole, so taxpayers bear most of the losses. Shareholders own all the "upside," meaning that if the bank recovers and increases in value, they will reap the benefits. In the takeover scenario, by contrast, managers lose their jobs, shareholders are wiped out, and any remaining losses are shared between taxpayers and creditors. (In a crisis, creditors' haircuts may have to be modest in order to protect those creditors from failing in turn.) Since the government now owns the bank, taxpayers can claim all the upside.

The takeover option was what the Treasury Department of Rubin and Summers (and Geithner, as treasury assistant secretary and then undersecretary for international affairs) strongly recommended for emerging market countries in the 1990s. Sick banks, they counseled, were at best a potential brake on economic recovery and at worst a serious macroeconomic risk; when investors fear a country's banks will collapse, they often abandon its other assets as well, triggering a sharp depreciation in its currency. Even if these banks happened to be run by close friends or relatives of the ruling elite, they could not be allowed to carry on in their existing form. Either they needed to be cut loose from government support, or they needed to be taken over and cleaned up, for the good of the economy.

After the Lehman bankruptcy, it became axiomatic that another major financial institution could not be allowed to fail in an uncontrolled manner that would spark panic in the markets. The question was whether the United States would follow the advice it had handed out a decade before and thousands of miles away. Ultimately, however, it was the taxpayer who would pay to rescue the financial sector—without getting very much in return.

Over the course of the financial crisis, the principal economic policymakers—first Paulson, Bernanke, and Geithner, then Geithner (as treasury secretary), Bernanke, and Summers (as director of the National Economic Council)—devised an impressive range of schemes to shore up the banking system. Their hard work and creativity cannot be doubted. But the common feature of these schemes was that they attempted to fill the gaping hole in bank balance sheets with government

subsidies, more or less crudely obscured.

The original purpose of TARP was to buy toxic assets from financial institutions. This would have the salutary effect of transferring risk from banks, which were choking on it, to the federal government, which is big enough to absorb it; besides, the official government theory was that the banks only faced a liquidity crisis, and that with its long time horizon the government could simply wait until the markets recovered. But this scheme faced a fundamental problem: if Treasury offered to pay the current market price for these assets, the banks would refuse to sell, since that would lock in losses they could not afford;* if Treasury paid enough to solve the banks' problems, that would constitute a massive subsidy from the taxpayer.[29]

Instead, the government chose to recapitalize banks by giving them cash in exchange for preferred shares (exploiting an ambiguity in the TARP legislation), beginning with the October 13 meeting. They were forced to do so by the markets, which were not convinced by the plan to buy toxic assets, and by announcements from the United Kingdom and several other European countries that they would recapitalize their banks. Putting government money into some banks is standard practice in emerging market financial crises, but the money typically comes with strict conditions in order to begin the reform process. In the United States, however, those conditions were missing. The government did not insist on market prices for its investments (as set by Warren Buffett with his investment in Goldman Sachs), fearing that some banks would decline to participate. Instead, the government bent over backward to make the deal attractive for the banks, charging below-market interest and eschewing any significant ownership—so shareholders, not taxpayers, would benefit when the banks recovered. As a result, for every $100 committed by Treasury at the October 13 meeting, $22 was a subsidy to the banking sector, according to a later report by the TARP Congressional Oversight Panel.[30] (One thing that was similar to emerging markets, however, was that politically connected banks were more likely to get their hands on cheap TARP capital, according to an analysis by Jowei Chen and Connor Raso.)[31]

As opposition to taxpayer-funded bailouts increased, the subsidy mechanisms became more complex. In November 2008, with Citigroup struggling to fend off concerns about its viability, the government announced a second bailout package. In addition to another $20 billion investment, the government agreed to guarantee a $306 billion pool of Citigroup assets against falls in value (after the bank absorbed the first $29 billion in losses). The government received additional preferred stock in exchange for the guarantee, but there is no question that the guarantee was a subsidy; if Citigroup had had to buy such a guarantee on the open market, it could not have afforded the price.

A similar asset guarantee was provided to Bank of America in January, apparently in exchange for its agreeing—under government pressure—to complete the acquisition of Merrill Lynch in December.[32] This time, the government guaranteed a $118 billion pool of assets in exchange for $4 billion in preferred stock. But in a bizarre twist, even though the deal was announced—reassuring the bank's creditors and stabilizing its financial position—it never actually closed (because of technical difficulties in identifying the specific assets to be guaranteed). As a result, the government never got the $4 billion in preferred stock, and when Bank of America's outlook improved it was allowed to walk away from the deal for a fee of $425 million.[33]

The government bailout of AIG, justified as a way of preventing complete chaos in the market for credit default swaps, turned out to be another subsidy to the banking sector. AIG's counterparties for those credit default swaps were primarily large banks. By committing $180 billion to keep AIG afloat, the government ensured that those counterparties would be paid in full for their winnings on the bets they had made with AIG. In March 2009, under pressure from lawmakers, AIG finally released some details of who had been made whole by government money: Goldman Sachs received $12.9 billion from AIG, Merrill Lynch $6.8 billion, Bank of America $5.2 billion, and Citigroup $2.3 billion, along with several major foreign banks.[34] This was cash that these banks would not have received had AIG gone bankrupt, or had it been subjected to an FDIC-style conservatorship.*

The AIG bailout illustrated the ability of major banks to take advantage of the government's situation. A handful of major banks had purchased credit default swaps from AIG to insure $62 billion in CDOs. The AIG bailout included a plan for the New York Fed to finance a new entity (Maiden Lane III†) to buy the CDOs so that AIG could then settle the credit default swaps.‡ Maiden Lane III paid $30 billion (the market price) to buy the CDOs from the banks, and AIG, under instructions from the New York Fed, then paid the banks $32 billion to retire the credit default swaps. The result was that the banks received 100 cents on the dollar in what amounted to a backdoor bailout—even though AIG, prior to its bailout, had been negotiating in an attempt to get the banks to accept as little as 60 cents on the dollar.[36] The banks were confident that the government would not force AIG into bankruptcy, and simply refused requests that they accept anything less. Neil Barofsky, the special inspector general for TARP, later criticized the New York Fed, which he said "refused to use its considerable leverage" to negotiate better terms.[37]

While TARP-funded recapitalizations and the AIG conduit managed to keep calamity at bay, they did little to address the major source of fear: the toxic assets that remained on bank balance sheets. In March, Geithner announced the Public-Private Investment Program (PPIP), another attempt to relieve banks of these assets. As always, the sticking point was the gap between the price that buyers were willing to pay for these assets and the price that banks were willing to accept. The PPIP closed the

gap through public subsidies. Private investors could lever up their own money with loans from the government. If the assets they bought fell in value, they could dump those assets on the government instead of paying back the loan; this limited their downside while giving them the amplified upside created by leverage.[38]

However, the PPIP failed to get off the ground. When the first transaction finally occurred in September, it was a sale by the FDIC of assets that it had inherited from a failed bank. (This made no sense, since the justification for the PPIP was to relieve *banks* of their toxic assets.) The banks themselves decided that they would be better off holding on to their toxic assets and hoping for the best, aided by an April 2 decision of the Financial Accounting Standards Board that made it even easier to set their own values for assets.

What finally turned the tide were the "stress tests" (officially the Supervisory Capital Assessment Program) that federal regulators conducted on nineteen leading banks in spring 2009, with results released on May 7.* The stated purpose of the exercise was to test whether the banks could withstand a severe economic downturn, quantify the amount of capital they would need in a worst-case scenario, and force them to raise that capital. But the more important purpose was to bolster confidence in the financial system. On one level, the exercise failed; many people doubted that the tests painted a true portrait of the banks' potential losses, especially when it came out that the Fed actually negotiated the results with the major banks, in some cases dramatically improving the banks' performance at the last minute.[39] (*Saturday Night Live*'s parody of Geithner, to some, seemed not too far from the truth: "Eventually, at the banks' suggestion, we dropped the asterisk and went with a pass/pass system. Tonight, I am proud to say that after the written tests were examined, every one of the nineteen banks scored a pass.")[40]

But on another level, the stress tests worked. For months, leading government figures had repeatedly assured the public that the banking system was secure. On April 21, Geithner testified, "Currently, the vast majority of banks have more capital than they need to be considered well capitalized by their regulators."[41] The stress tests were a way of committing the government to back those words with money. Once the government had certified the banks' balance sheets, and once the banks had raised the capital the government demanded, the government would have no excuse not to bail them out if needed. This was not entirely a good thing: once the pressure to get their houses in order was off, the banks were in no rush to unload their toxic assets.

The strengthened government guarantee was one ingredient pulling the megabanks back from the abyss. Another was reduced competition. Not only did Bear Stearns, Lehman Brothers, Merrill Lynch, Washington Mutual, and Wachovia all vanish, but an entire class of nonbank mortgage lenders evaporated with the housing bubble. With fewer competitors, the survivors could sweep up larger shares of the market and demand higher margins and fees. And a third factor was the cheap money being pumped into the economy by the Federal Reserve. Banks' primary raw material is money. Less competition and cheap money meant higher revenues and lower costs at the same time.

With low interest rates, banks could raise money from depositors virtually for free; they could borrow cheaply from each other; they could borrow cheaply at the Fed's discount window; they could sell bonds at low interest rates because of FDIC debt guarantees; they could swap their asset-backed securities for cash with the Fed; they could sell their mortgages to Fannie and Freddie, which could in turn sell debt to the Fed; and on and on. Because so much cash was easily available to the banks, they could not suddenly run out of money. And because short-term interest rates fell further than long-term interest rates, the basic business of banking—borrowing short and lending long—became more profitable. The indefinite government lifeline gave the banks time to recapitalize themselves with profits from current operations.

Effectively, the government's strategy was to bail the banks out of their problems by helping them make large profits, juiced by reduced competition and cheap money, to plug the ever-widening hole created by their toxic assets. As part of its stress tests, the Federal Reserve concluded that the four largest banks—Bank of America, Citigroup, JPMorgan Chase, and Wells Fargo—stood to lose another $425 billion on existing assets through the end of 2010, but would fill more than half of that hole with $256 billion in profits over the same period.[42] For the stronger banks, such as JPMorgan Chase and Goldman Sachs, the result was a quick return to profitability and the appearance of health; the weaker ones, such as Citigroup and Bank of America, gained time to wait for an economic recovery to bail them out of their bad loans.

Repeated public assurances, the stress test results, and the earlier emergency bailouts of Citigroup and Bank of America made it clear not only that the government would not let a major bank fail, but that the government would bail out banks in their existing form, with their existing management, and without imposing haircuts on bank creditors. Figure 6-1 shows the perceived likelihood that major banks would go bankrupt, as measured by the price of credit default swap protection on their debt; each time the government intervened, the market's fears ebbed, until finally the stress tests broke the year-long fever. That was what Wall Street needed to hear: they could go back to doing business as usual, and Washington would be there if things went wrong. A panic that began with an attempt to reduce moral hazard by letting Lehman fail only ended when everyone was convinced that the government would not let another major bank fail—magnifying moral hazard to an unprecedented degree. And as the real economy began to bottom out over the summer, it became easier and easier to make money again. But this was only true for the major banks; in the real economy, it became harder and harder to get a loan. According to the Federal Reserve's survey of bank loan officers, every type of loan became harder to get in every quarter of 2008 and through the first three quarters of 2009.[43]

In short, Paulson, Bernanke, Geithner, and Summers chose the blank check option, over and over again. They did the opposite of what the United States had pressed upon emerging market governments in the 1990s. They did not take harsh measures to shut down or clean up sick banks. They did not cut major financial institutions off from the public dole. They did not touch the channels of political influence that the banks had used so adeptly to secure decades of deregulatory policies. They did not force out a single CEO of a major commercial or investment bank, despite the fact that most of them were deeply implicated in the misjudgments that nearly brought them to catastrophe. Summers was aware of the irony, although he disagreed that the situations were exactly parallel. "I don't think I would quite accept the characterisation that we're in the position that the Russians were in in 1998," he said in a 2009 interview, because the United States did not face the problem of foreign capital flight. But, to his credit, he acknowledged,

> There have been moments, certainly, when I understood better some of the reactions of officials in crisis countries now than one was able to from the outside at the time. It is easier to be for more radical solutions when one lives thousands of miles away than when it is one's own country.[44]

The total cost of all those blank checks is virtually incalculable, spread across the more or less direct subsidy programs (preferred stock purchases, asset guarantees, and so on) and the emergency liquidity and insurance programs to unfreeze the markets for commercial paper, asset-backed securities, or bank debt. It is incalculable because the different types of support—lending commitments, asset guarantees, preferred stock purchases, and such—cannot simply be added up. At the upper end of the relevant ballpark, the special inspector general for TARP estimated a total potential support package of $23.7 trillion, or over 150 percent of U.S. GDP.[45] This represents the theoretical potential liabilities of the government; the net cost will be far lower, since not all lending commitments will be used up, most loans will be paid back, most preferred shares will be bought back, most of the assets the government has guaranteed will not become worthless, and so on.

In the end, the government's strategy succeeded in bringing the financial system back from the brink of ruin, although not in restoring that system to health and stimulating lending to the real economy. There are three crucial steps in responding to a financial crisis: ending the panic, preventing economic activity from collapsing, and laying the groundwork for a sustainable recovery. The government largely succeeded in the first step, and the stimulus package passed in early 2009 helped with the second step. But the unconditional support provided to the financial system only exacerbated the weaknesses and incentives

that had created the crisis in the first place.

Despite the tremendous cost of bailing out the financial system, the cost of letting the system collapse would probably have been even higher. But was bailing out Wall Street the only way to avoid disaster?

The beginning of 2009 saw a raging public debate between the blank check option and the takeover option. The key question was not whether to intervene; virtually everyone involved acknowledged that the megabanks were too big to fail, because if any one of them collapsed the system as a whole might collapse. The question was what to do about it. The government argued that the banks' fundamental situation was not that bad—banks faced a "liquidity crisis" caused by short-term fear, not a "solvency crisis" caused by severe economic losses—and that the best way to contain that fear was to keep the banks going in their current form; anything more drastic would only cause panic.

The opposing view, put forward by many people including Nobel Prize laureates Paul Krugman and Joseph Stiglitz (and non–Nobel laureates like us), was that some major banks were deeply sick and that successive bailouts amounted to vast giveaways of taxpayer money that would do little to solve either the short-term or the long-term problems in the financial sector. As Krugman said, "Every plan we've heard from Treasury amounts to the same thing—an attempt to socialize the losses while privatizing the gains."[46] But because the government only had enough money to keep the banks afloat, it was not actually restoring them to the health necessary for them to start lending again. The problem was both political and economic. In Krugman's words:

> As long as capital injections are seen as a way to bail out the people who got us into this mess (which they are as long as the banks haven't been put into receivership), the political system won't, repeat, won't be willing to come up with enough money to make the system healthy again. At most we'll get a slow intravenous drip that's enough to keep the banks shambling along.[47]

By leaving the banks in the hands of their existing managers and going out of its way to minimize its own influence, the government was ensuring that it had no way to encourage banks to do anything other than hoard their cash, and no way to affect bank behavior in the future. Attempts by the Federal Reserve to stimulate the economy were absorbed by what Richard Fisher, president of the Federal Reserve Bank of Dallas, called "the Blob" of large, sick banks. "Those banks with the greatest toxic asset losses were the quickest to freeze or reduce their lending activity," Fisher said; in addition, "the dead weight of [the megabanks'] toxic assets diminished the capacity of markets to keep debt and equity capital flowing to businesses and scared investors away."[48] Although bank bailouts did prevent economic calamity, they would do little to ensure financial stability or economic prosperity.

Krugman, Stiglitz, and others argued that the government should take over banks, clean them up so they would function normally, and sell them back into private hands when possible, as in an FDIC intervention. In a February 2009 interview, Stiglitz said, "Nationalization is the only answer. These banks are effectively bankrupt."[49] Other prominent supporters of a government takeover included economics professors Nouriel Roubini and Matthew Richardson and Dean Baker of the Center for Economic and Policy Research.[50] While takeovers would be a form of temporary nationalization, no one ever refers to FDIC takeovers that way; instead, they are thought of as a government-managed bankruptcy process. A major bank such as Citigroup might have required government conservatorship for months or years, but the goal would have been to restore private ownership when economic conditions allowed. There were both economic and political arguments for this course of action.

The immediate economic argument was that sick banks could only be thoroughly cleaned up via a takeover. Toxic assets needed to be removed from bank balance sheets; but as long as a bank remained independent, any such transaction had to be negotiated, and the bank's managers (representing the shareholders) could simply hold up the government for a high price, knowing that if the bank failed, other people would be left holding the bag. If the government took over a bank, however, it could transfer the toxic assets to a separate government entity without negotiation, restore the bank to health by adding new capital, and return it to normal operation. Management would be replaced and shareholders wiped out, leaving the bank in the hands of taxpayers, who would get at least some of their money back when the bank could be sold into private hands. (Alternatively, the government could have simply bought a struggling bank at market value; at one point in March 2009, the market value of all of Citigroup's common stock fell below $6 billion.)[51] The toxic assets could be parked on the balance sheet of the U.S. government, which could hold them indefinitely and, if necessary, absorb the losses they entailed.

The longer-term economic argument was that a takeover was necessary to remove moral hazard—the temptation for bank executives (and shareholders) to take risky gambles, knowing that they would benefit from success but that taxpayers would bear the losses in case of failure. After the Lehman bankruptcy, the government's policy was that no major bank would be allowed to fail—and every bank CEO knew it—even while smaller banks were failing by the dozens. By contrast, major bank takeovers would send the message that there was a penalty for failure, giving executives and shareholders the incentive to avoid excessive risk, and giving creditors the incentive to be more careful with their money.

Taking over sick megabanks would also have political benefits. As in Korea a decade before, effective reform would require confronting the political roots of the crisis—the disproportionate political power of Wall Street. The right time for that confrontation was when the banks were at their weakest and most dependent on government aid. Bailing out the banks unconditionally put the government in the position of having to ask for favors later—favors that the banks would have no reason to return. By contrast, taking them over would have weakened or eliminated their ability to resist the regulatory reforms necessary to ensure long-term financial stability and economic growth.

Finally, takeover was only fair. Bankers who had run their institutions into the ground would no longer collect seven- or eight-figure bonuses made possible only by government bailouts. Shareholders who had gambled on highly leveraged banks would lose their money. Creditors who had lent blindly would lose part of their money. Taxpayers footing the largest part of the bill would at least have the possibility of making money as banks recovered. This is how capitalism is supposed to work. Failure should be punished, not rewarded. The government should be the backstop protecting society against a financial collapse, but it should exact a price for that protection. Reflecting on the emerging market crises of the 1990s in his 2000 American Economics Association lecture, Summers had emphasized, "Prompt action needs to be taken to maintain financial stability, by moving quickly to support healthy institutions and by intervening in unhealthy institutions. The loss of confidence in the financial system and episodes of bank panics were not caused by early and necessary interventions in insolvent institutions."[52] Instead, by providing serial bailouts with no meaningful conditions attached, the Bush and Obama administrations both rewarded failure and backed away from the tough medicine needed to restore a well-functioning financial sector.

As we wrote in *The Atlantic* in March 2009, "The challenges the United States faces are familiar territory to the people at the IMF. If you hid the name of the country and just showed them the numbers, there is no doubt what old IMF hands would say: nationalize troubled banks and break them up as necessary."[53] However, the administration took pains to deny that this was even a plausible option. In a February interview, when asked about "nationalization," Geithner responded, "It's not the right strategy for the country for basic practical reasons that our system will be stronger if it remains in private hands with support from the government to make sure those institutions can play their critical role going forward."[54] Then and elsewhere, Geithner carefully avoided even using the word "nationalization," as if saying it might unnerve the private sector. The administration was successful in sending the message that no major banks would be taken over on its watch, and it was a message that Wall Street heard loud and clear.

Another issue that Wall Street cared deeply about was executive compensation. By the time the Obama administration came into office, one sore point with the public was that banks receiving government assistance were subject only to weak limits on compensation (boards of directors had to ensure that senior executives' compensation packages did not motivate them to take excessive risks, bonuses based on materially inaccurate information had to be clawed back, and golden parachutes to top executives were prohibited[55]). To the public, that meant that taxpayer money could pass straight through to bankers' Ferraris and vacation homes in the Hamptons. Some administration insiders, including top political adviser David Axelrod, pressed for greater restrictions on compensation.[56] Because of a provision of the economic stimulus package passed by Congress in February, the final rule issued in June 2009 was slightly stricter—limiting the bonuses payable to certain executives, requiring that they be paid in long-term restricted stock, and requiring a nonbinding shareholder vote on executive compensation[57]—but tight restrictions and close monitoring applied only to a handful of companies receiving "exceptional assistance" from the government.[58] Even the relatively mild limits were too much for most of the megabanks, who rushed to pay back their TARP money as quickly as possible—weakening their balance sheets (by paying back cash they didn't need to pay back) so they could say they were free of government support, even as they profited from the cheap money supplied by the Federal Reserve. The main effect of the rule was to tilt the playing field against the banks that had received exceptional assistance (Citigroup and Bank of America) and therefore were subject to stricter compensation limits, making it harder for them to attract and retain key people. Any systematic attempt to curb the perverse incentives created by banking industry compensation practices was kicked down the road to a future regulatory reform bill.

The Obama administration did not uniformly support banks' interests, but what the banks could not win in the White House, they often won in Congress. On February 18, President Obama announced his "Homeowner Affordability and Stability Plan," which contained a provision allowing judges to modify the terms of home mortgages for borrowers who were in bankruptcy. The idea was that if a borrower's house was worth far less than the mortgage, a bankruptcy judge should be able to reduce the mortgage—just as the judge could reduce the amount owed to almost all other creditors. The banking lobby succeeded in killing this "cramdown" provision in the Senate, with the banks and their industry associations refusing even to negotiate with Senator Richard Durbin while the Obama administration remained on the sidelines. Instead, the bill contained a separate provision *reducing* the amount that banks had to pay the FDIC for deposit insurance.[59] This exercise in legislative muscle-flexing showed the continuing power of the big banks on Capitol Hill. Even as they depended on government investments, debt guarantees, and liquidity programs for their survival, they actually increased their lobbying expenditures to fight off potential regulatory reforms.[60]

On issue after issue, the big banks got what they wanted, and the taxpayer got the bill. The justification for these policies was that anything that threatened to weaken the banks might trigger a resurgence of the panic of September-October 2008. But the result was the same. The large banks used their political power to protect their money machines from government interference, and when those machines exploded they used their size and importance to force the government to bail them out.

BUSINESS AS USUAL

In the end, the major banks got business as usual. The shakeout of 2008 left the big banks even bigger. Bank of America absorbed Countrywide and Merrill Lynch and saw its assets grow from $1.7 trillion at the end of 2007 to $2.3 trillion in September 2009. JPMorgan Chase absorbed Bear Stearns and Washington Mutual and grew from $1.6 trillion to $2.0 trillion. Wells Fargo absorbed Wachovia and grew from under $600 billion to $1.2 trillion.[61] This growth occurred against a backdrop of falling asset values and de-leveraging, which meant that most banks were cutting their new lending and getting smaller.

Consolidation among the big banks and the collapse of the nonbank mortgage lenders meant much larger market shares for the fewer but bigger megabanks. Bank of America, JPMorgan Chase, and Wells Fargo all had to be exempted from a federal rule prohibiting any single bank from holding more than 10 percent of all deposits in the country, and from Department of Justice antitrust guidelines intended to limit monopoly power in specific metropolitan regions. By mid-2009, those three banks and Citigroup together controlled half the market for new mortgages and two-thirds of the market for new credit cards.[62] Derivatives, which had always been dominated by fewer than twenty dealers, became even more concentrated. At the end of June 2009, five banks together had over 95 percent of the market for derivatives contracts traded by U.S. banks, led by JPMorgan Chase's 27 percent share.[63]

The government's insistence that large banks would not be allowed to fail worked only too well. Large banks were able to borrow money at rates 0.78 percentage points more cheaply than smaller banks, up from an average of 0.29 percentage points from 2000 through 2007. In the banking business, where profits depend on the spread between the interest rate you receive and the interest rate you pay, 0.78 percentage points are a huge financial advantage.[64] And what were large banks doing with their newfound market power? They were boosting profits any way they could—increasing fees on deposit accounts, even while their smaller competitors were reducing fees.[65]

For JPMorgan Chase, the payoff was blowout profits fueled by both its huge footprint in consumer banking and its growing investment banking business. Bank of America and Citigroup, though still fundamentally troubled, managed to keep up the appearance of profits, in part through one-time asset sales, in part through accounting gimmicks. Most surprisingly to the casual observer, the investment banking business, which had seemed on the brink of death in September 2008, roared back to life (even if the major stand-alone investment banks were now technically bank holding companies). In the first quarter of 2009, bond trading departments took advantage of high volatility in the markets to rake in large fees and make money in proprietary trading. There was also widespread speculation (difficult to confirm, given the secretive nature of trading operations) that bank trading profits were boosted by taking advantage of the fact that AIG was trying to unwind its large positions rapidly—which meant that the banks were making money at the expense of a taxpayer-owned company.*

In the second quarter, things got even better. Goldman Sachs reported its largest quarterly profit ever—$3.4 billion—on the backs of a record performance from its bond trading division and $700 million in stock underwriting.[67] Those bond trading profits were given a helping hand by the Federal Reserve, which was buying large volumes of securities (to provide liquidity and stimulate the economy) while telegraphing its moves to Wall Street. As one asset management executive said, "You can make big money trading with the government. The government is a huge buyer and seller and Wall Street has all the pricing power."[68] And the $700 million was in part the result of federal bailouts; as the government ordered other banks to issue new stock to raise capital, they were forced to turn to the few remaining investment banks. JPMorgan Chase, Goldman Sachs, and Morgan Stanley alone accounted for 42 percent of the market for equity underwriting in the first half of 2009.[69] Finally, Goldman was making money the oldfashioned way—by taking on more risk. As the bank's president, Gary Cohn, said in August 2009, "Our risk appetite continues to grow year on year, quarter on quarter, as our balance sheet and liquidity continue to grow."[70] And Goldman's value-at-risk—a quantitative measure of the amount it stood to lose on a given day—after dipping slightly in summer 2008, continued to climb throughout the crisis to levels in 2009 five times as high as in 2002.[71]

However, the clearest indication that Wall Street was back to business as usual was the amount of money earmarked for bonuses. In the first half of 2009, Goldman Sachs set aside $11.4 billion for employee compensation—an annual rate of over $750,000 per employee and near the record levels of the boom. Even if the government's strategy was to let the banks earn their way out of their problems, that strategy was being undermined by a bonus culture that diverted the excess profits to employees rather than to capital reserves. High risk and huge payouts—nothing changed, except a strengthened government guarantee. Defending the huge bonuses in St. Paul's Cathedral in London in October 2009, Goldman Sachs executive Brian Griffiths went Gordon Gekko one better by invoking Jesus: "The injunction of Jesus to love others as ourselves is a recognition of self-interest.… We have to tolerate the inequality as a way to achieving greater prosperity and opportunity for all."[72] Goldman CEO Lloyd Blankfein even claimed to be "doing God's work" (because banks raise money for companies who employ people and make things).[73]

The rest of us were not so lucky. While a second Great Depression was averted, the collateral damage to the real economy

was enormous. The collapse of the housing bubble tipped the economy into recession in December 2007, leading to the loss of 1.1 million jobs in the first eight months of 2008.[74] The fall of Lehman Brothers in September 2008 and the ensuing panic triggered a severe economic contraction, leading to the loss of another 5.8 million jobs over the next twelve months as the economy shrank by 4 percent.[75] The unemployment rate doubled from 4.9 percent at the beginning of the recession to 10.2 percent by October 2009; the broadest measure of unemployment, including people who gave up looking for a job and people working part-time who would prefer to work full-time, doubled from 8.7 percent to 17.5 percent—more than one in every six people in the broad workforce.[76]

As the economy declined sharply, the sudden collapse in tax revenues left government finances in disarray. State and local governments resorted to severe cutbacks in services. The federal government dedicated $800 billion in new spending and tax cuts to stimulate the economy. However, stimulus spending and lower tax revenues pushed the 2009 federal deficit up to $1.6 trillion, or 11 percent of GDP, more than doubling the previous postwar record.[77] The long-term effect of the financial crisis and recession is even greater. In January 2008, just as the economy was tipping into recession, the Congressional Budget Office (CBO) projected that, by the end of 2018, U.S. government debt would fall to $5.1 trillion, or 22.6 percent of GDP. Surveying the wreckage in August 2009, the CBO projected that debt at the end of 2018 would rise to $13.6 trillion, or 67.0 percent of GDP—a difference of $8.5 trillion.[78] This should come as no surprise; Carmen Reinhart and Kenneth Rogoff have shown that, on average, modern banking crises lead to an 86 percent increase in government debt over the three years following the crisis.[79]

The financial crisis and the government's emergency response also increased the likelihood of two bleak scenarios. First, the enormous amount of liquidity that the Federal Reserve poured into the economy created the long-term potential for high inflation; if the Fed cannot "mop up" that liquidity when the economy recovers, all that excess money could make dollars less valuable, driving up prices.

Second, the vast increase in the total national debt brought us closer to the point where it could become more difficult to raise money by issuing new government debt. Should that happen, the government will have to pay higher interest rates to borrow money, and those higher interest rates will spread throughout the entire economy, slowing economic growth. In a worst-case scenario, the government may have to raise money in foreign currencies, undermining one of our traditional advantages over much of the rest of the world. This is unlikely to occur solely as a result of the recent financial crisis; before the crisis, the United States was only moderately indebted by international standards and had the capacity to absorb one shock without seriously affecting our ability to borrow money. Whether we can absorb another such shock is another question. The United States did not look like an emerging market when the crisis began, but it has already become more like one.

J. Paul Getty is reputed to have said, "If you owe the bank $100, that's your problem. If you owe the bank $100 million, that's the bank's problem." The bank cannot afford a loss of $100 million, and therefore will do anything to help you avoid default—and that gives you power.

In 2008–2009, the tables turned. It was the major banks who were struggling with their debts, and it was the U.S. government that could not afford to let them fail, because of the damage that would inflict on the real economy and on tens or hundreds of millions of people. (Small banks, however, were like people who owed $100.) This meant that when the banks faced off with the government, they held all the cards. As Barney Frank put it, "All these years of deregulation by the Republicans and the absence of regulation as these new financial instruments have grown have allowed them to take a large chunk of the economy hostage. And we have to pay ransom, like it or not."[80]

The fact that their failure could entail the loss of millions of jobs gave the banks the power to dictate the terms of their rescue. If the government insisted on paying market prices for toxic assets, or insisted on taking majority control, the banks could simply refuse to go along, secure in the knowledge that the government would have to come back to the table. In the end, the government had more to lose from major bank failures than did the bankers themselves, who had already made their money. Citigroup CEO Vikram Pandit, for example, made $38 million in 2008[81] on top of the $165 million he made by selling his hedge fund to Citigroup in 2007.[82] At most they would suffer a reputational blow should their banks fail—which they could always blame on market conditions and the failure of the government to come to their aid. This was the problem with the strategy of negotiating with Wall Street; Wall Street held all the cards.

But that is not a complete explanation, because there is little evidence that the government attempted to force the issue. It was not only that the government had a weak hand; it was that the government negotiators came to the table largely in agreement with the bankers' view of the world. And it wasn't just a few key people. Paulson, of course, was the former head of Goldman Sachs, and his aides at Treasury included Robert Steel, Steve Shafran, and Neel Kashkari from Goldman. In summer 2008, when he realized he needed reinforcements to fight the financial crisis, he summoned Dan Jester and Ken Wilson, also Goldman veterans.[83] When faced with the potential insolvency of Fannie Mae and Freddie Mac in August 2008, Paulson hired Morgan Stanley (for a nominal fee) to analyze the two GSEs; Morgan Stanley was also hired by the Federal Reserve Bank of

New York to advise on the AIG bailout.[84] Given the urgency of the situation and the technical details involved, it made sense for the government to hire outside help. But that help could only come from one place: Wall Street.

What is more remarkable is that the policies of the Bush administration were largely carried over into the Obama administration, despite the enormous policy differences between George W. Bush and Barack Obama on almost every issue. This is because by 2009, the economic policy elite of the *Democratic* Party was fully won over to the idea that finance was good.

During the Democratic primary campaign, Obama's chief economic adviser was Austan Goolsbee, an economics professor without a long track record as a party insider. But after Obama won the election, he turned to a Democratic establishment that was formed in the Clinton years, largely under the tutelage of Robert Rubin. Michael Froman, who was Rubin's chief of staff at Treasury and followed him to Citigroup, and James Rubin, Rubin's son, were both members of Obama's transition team.[85] (Froman was also an associate of Obama's from their law school days, independently of Rubin; after the transition, he became a member of both the National Economic Council and the National Security Council.) Geithner, who had built close relationships with Wall Street CEOs during his five years as president of the New York Fed,[86] became treasury secretary. Summers, most recently a managing director of the hedge fund D.E. Shaw, became director of the NEC. Peter Orszag, Clinton economic adviser and director of Rubin's Hamilton Project, became head of the Office of Management and Budget; Gary Gensler, treasury undersecretary for domestic finance under Summers (and former Goldman partner), became head of the CFTC; Mary Schapiro, first head of the CFTC under Clinton and later head of the Financial Industry Regulatory Authority, the financial industry's chief *self-regulatory* body, became head of the SEC; Neal Wolin, treasury deputy counsel and general counsel under Rubin and Summers, became deputy treasury secretary; Michael Barr, special assistant and deputy assistant secretary in the Rubin Treasury, became assistant secretary for financial institutions; Jason Furman, director of the Hamilton Project after Orszag, became deputy director of the NEC; and David Lipton, treasury undersecretary for international affairs during the Asian financial crisis and later Citigroup executive, also became one of Summers's deputies at the NEC. Even President Obama's chief of staff, Rahm Emanuel, had a similar background, having worked both as a Clinton adviser and as an investment banker at Wasserstein Perella.

Geithner's counselors as treasury secretary included Lee Sachs from the Clinton Treasury (and most recently a New York hedge fund) and Gene Sperling, Rubin's successor as director of the NEC (and most recently a highly paid adviser to a Goldman Sachs philanthropic project). The new blood that did not come from the Clinton establishment came largely from Wall Street. Mark Patterson, Goldman Sachs's chief lobbyist, became Geithner's chief of staff; Geithner's counselors also included Lewis Alexander, chief economist at Citigroup, and Matthew Kabaker from the Blackstone Group.[87] Assistant secretary for financial stability Herbert Allison was president of Merrill Lynch before heading TIAA-CREF (an asset manager) and Fannie Mae. Meanwhile, at the New York Fed, the board of directors picked William Dudley, a Goldman partner and then one of Geithner's lieutenants, to replace Geithner as president.

There is nothing sinister about the appointment of so many veterans of the Rubin Treasury; according to usual Washington practice, Obama and his lieutenants were calling on people who had gained experience in the previous Democratic administration.[88] And the fact that people worked under Rubin does not mean that they automatically sided with Wall Street on every issue. Some of them spent 2009 fighting for policies that were not friendly to Wall Street. Michael Barr, for example, was a strong advocate for a new Consumer Financial Protection Agency (CFPA), and Gary Gensler worked to plug loopholes in financial regulation bills as they worked their way through Congress.[89] But the economic brain trust was largely shaped in two complementary environments: Wall Street and the Rubin Treasury. And while the Obama administration did not close ranks with the major banks, it also does not seem to have strongly considered policies that seriously threatened the power and profits of the major banks (with the possible exception of the CFPA).

The administration also included Democratic economists from outside the Wall Street–Washington corridor, but they were outnumbered and generally (though not always) placed in less central positions. Respected academic macroeconomist Christina Romer became chair of the Council of Economic Advisers; Alan Krueger, an economics professor who served in the Labor Department under Robert Reich, became a treasury assistant secretary; Jared Bernstein became chief economic adviser to Vice President Joseph Biden; and Goolsbee became director of the President's Economic Recovery Advisory Board, a new organization that failed to gain any real influence. Even Paul Volcker, perhaps the most respected Democratic economist available, who endorsed Obama back in January 2008 when most of the establishment was backing Hillary Clinton, became chair of the Economic Recovery Advisory Board and seemed to fade from sight; in October 2009, responding to reports that his influence was fading, Volcker said, "I did not have influence to start with."[90]

Not only did key policymakers have long-standing ties to Wall Street, but during the crisis they gave tremendous access to their Wall Street contacts. In his first seven months in office, Geithner's calendar shows more than eighty contacts with Goldman CEO Lloyd Blankfein, JPMorgan CEO Jamie Dimon, Citigroup CEO Vikram Pandit, or Citigroup chairman Richard Parsons.[91] While it is necessary for the treasury secretary to talk to Wall Street executives during a financial crisis, he had more contacts with Blankfein than with Senate Banking Committee chair Christopher Dodd and more contacts with Citigroup

than with House Financial Services Committee chair Barney Frank. (This was a far cry from the tone of the Roosevelt administration in 1933, of which Arthur Schlesinger wrote, "When one remembered both the premium bankers put on inside information and the chumminess they had enjoyed with past Presidents and Secretaries of the Treasury, the new chill in Washington was the cruelest of punishments.")[92] In a world where access is a prerequisite for influence, Wall Street had access to the people who mattered, when it mattered.

As a result, economic policy in 2009, just as in 2008, was set by a group of people who, despite their considerable intelligence, experience, and integrity, seemed to believe that the banks were fundamentally sound and only needed an injection of confidence; that each subsidy to the banking sector was justified because the costs of not making the subsidy would be worse; that government takeover of major banks was so anathema to the American way that it would trigger panic; that meaningful constraints on banks' activities would inhibit economic growth; and that meaningful constraints on bankers' compensation would send them fleeing to unregulated hedge funds or overseas, leaving the American economy to suffer as a result. But this is not surprising, because everybody believed all these things—everybody, that is, in the New York and Washington elite. Over thirty years, Wall Street had plied Washington with tantalizing tales of financial innovation and efficient markets while pouring rivers of money into politicians' campaign funds and lobbyists' expense accounts. In 2008 and 2009, it all paid off.

As Michael Lewis put it in 2009,

> It does feel a lot to me like the process has been queered by political influence, and it's a very curious kind of political influence. Because it isn't maybe always as simple as bribery, campaign contributions, and that kind of thing. I think that we've had twenty-five years of the Goldman Sachses of the world ruling the world, and the people like Tim Geithner, when they leave office, the way they make their living … is to go to work for a financial institution for huge sums of money; that people have trouble getting their mind around a world where that's not the way the world works, and there is maybe a slight quickness to believe that the world can't function without Goldman Sachs.[93]

Can it?

* All nine banks were also represented at the March 27, 2009, meeting discussed in the Introduction, except for Merrill Lynch, which was acquired by Bank of America in the interim.

* Only if the bank failed to pay its dividends six times would the government have the right to elect directors.

* The discount rate is the rate at which banks may borrow money directly from the Federal Reserve; the federal funds rate is the rate at which banks borrow money from each other overnight.

* The junior tranches of a CDO bore the first losses from the entire pool of mortgages or mortgage-backed securities that went into the CDO, so a default rate of only 6 percent could render an entire tranche of CDO securities worthless. Although securitization spread risk among many investors, it also concentrated risk into the junior tranches.

† A bank's balance sheet is supposed to record what its assets are worth; a write-down is a reduction in the recorded value of an asset. In practice, the rules on what values to use for assets can vary depending on many factors. Only some assets need to be "marked to market," meaning that their values should be adjusted to current market prices.

* AIG's derivatives contracts gave its counterparties the right to demand collateral to protect them against the possibility that AIG might not be able to honor those contracts. The amount of collateral the counterparties could demand went up as AIG's credit rating went down.

* In the case of General Motors, the government used its power as the only source of financing to force out CEO Rick Wagoner and to dictate "haircuts" for creditors—steps it did not take with any major commercial or investment bank.

* Commercial banks could record some assets on their balance sheets at high "book values" even if they could not actually sell them at those prices. So on paper, banks remained solvent—their assets exceeded their liabilities, whether or not they could actually sell the assets for enough to cover the liabilities. Selling assets would force banks to recognize their losses; not selling them allowed them to pretend that the assets had not deteriorated in value.

* Goldman Sachs insisted that it received no net benefit from the money it received from AIG, because it was fully hedged, primarily via credit default swaps on AIG itself; this claim has been disputed.[35]

† Maiden Lane II was the vehicle for a separate component of the AIG bailout.

‡ The purpose of the transaction was to limit AIG's potential losses. With the credit default swaps outstanding, it could have been liable for the full face value of the CDOs. After the credit default swaps were retired, the remaining risk in the CDOs was held by Maiden Lane III; AIG's losses on Maiden Lane III were limited to its contribution of $5 billion, with any further losses being taken by the New York Fed.

* The stress tests included eleven of the thirteen banks present at the March 27, 2009, meeting at the White House: American Express, Bank of America, Bank of New York Mellon, Citigroup, Goldman Sachs, JPMorgan Chase, Morgan

Stanley, PNC, State Street, US Bank, and Wells Fargo (Freddie Mac and Northern Trust were omitted). The other eight institutions subjected to the tests were BB&T, Capital One, Fifth Third, GMAC, KeyCorp, MetLife, Regions Bank, and SunTrust.

* If a trader wants to exit a large position quickly, he is at the mercy of the people he is trading with, who can essentially name their price. An e-mail from one trader, published by the blog *Zero Hedge,* included this excerpt: "During Jan/Feb AIG would call up and just ask for complete unwind prices from the credit desk in the relevant jurisdiction. These were not single deal unwinds as are typically more price transparent—these were whole portfolio unwinds. The size of these unwinds were [*sic*] enormous, the quotes I have heard were 'we have never done as big or as profitable trades—ever.' "[66]

THE AMERICAN OLIGARCHY

Six Banks

> What all this amounts to is an unintended and unanticipated extension of the official "safety net." … The obvious danger is that with the passage of time, risk-taking will be encouraged and efforts at prudential restraint will be resisted. Ultimately, the possibility of further crises—even greater crises—will increase.

> If they're too big to fail, they're too big.
>
> —Alan Greenspan, October 15, 2009[2]

Between 1985 and 1992, over 2,000 banks failed in the savings and loan crisis, a consequence of deregulation, mismanagement, and fraud. Those S&Ls had been largely overseen by the Federal Home Loan Bank Board, which had failed to shut down struggling thrifts early in the 1980s, instead hoping that they could grow into solvency by expanding into more profitable (and riskier) businesses.[3] In response, Congress passed the Financial Institutions Reform, Recovery, and Enhancement Act of 1989. Among other things, it abolished the Federal Home Loan Bank Board and replaced it with the Office of Thrift Supervision (OTS). On August 9, 1989, President George H. W. Bush signed the bill, saying, "This legislation will safeguard and stabilize America's financial system and put in place permanent reforms so these problems will never happen again."[4]

NPR correspondent Chana Joffe-Walt tells the story:

> I talked to several people who worked for that predecessor agency, the Bank Board, and they describe that on that day, the day the OTS was created, they left the office, these agency employees, and they walked across the street to a hotel. They turned on the TV, and they sat and watched the first President Bush stand up at a podium and declare, "Never again will America allow any insured institution [to] operate without enough money." And then the agency employees watched as the President trashed their agency. The press conference ended, they turned off the TV, left the hotel, crossed the street, and went back to work. Pretty soon someone came by and changed the sign: The Office of Thrift Supervision.[5]

This, of course, is the same Office of Thrift Supervision that would be responsible for American International Group, Countrywide, and Washington Mutual in the 2000s.

At this crucial juncture in our history, as America emerges from a deep recession into an uncertain economic future, and in the wake of an epochal bailout of our largest banks, we must reform the financial system that made possible the financial and economic crisis that cost millions of people their jobs and added trillions of dollars to the national debt. The last few years have proven that our financial sector and its political influence are a serious risk to our economic well-being, and without significant change there is no reason to believe we will not soon experience the next boom, the next bust, and the next president explaining to the American people that he must rescue Wall Street in order to save Main Street. And significant change will require addressing the disproportionate wealth and power of a handful of large banks at the pinnacle of the financial sector.

Simply asking bankers to behave differently will not work; the solution can only come by changing the rules of the financial system, which requires government action. Five days after President Obama's election, his chief of staff, Rahm Emanuel, said, "Rule one: Never allow a crisis to go to waste. They are opportunities to do big things."[6] But more than a year after the collapse of Lehman Brothers, even relatively moderate legislation to reform the financial sector was still stuck in Congress.

The Obama administration attempted to show that it was serious about change. "The industry needs to show that they get it on the compensation issue," Obama said at the March 27, 2009, White House meeting discussed in the Introduction. "Excess is out of fashion." (According to *The New York Times,* "The bankers nodded, but made no firm commitments.")[7]

On June 17, 2009, President Obama unveiled what he called "a sweeping overhaul of the financial regulatory system, a transformation on a scale not seen since the reforms that followed the Great Depression."[8] He proposed stricter oversight of financial institutions, new regulations for securitization and over-the-counter derivatives, increased consumer protections, and new government powers to cope with a crisis.[9] Three months later, standing in the heart of the Manhattan financial district, Obama promised:

> We will not go back to the days of reckless behavior and unchecked excess that was at the heart of this crisis, where too many were motivated only by the appetite for quick kills and bloated bonuses.… [T]he old ways that led to this crisis cannot stand. And the extent that some have so readily returned to them underscores the need for change and change now.

History cannot be allowed to repeat itself.[10]

But despite the president's lofty language, many of his proposals represented only incremental reform. They did little to address the problem at the heart of the financial system: the enormous growth of top-tier financial institutions and the corresponding increase in their economic and political power. In place of bold measures, the administration preferred technical solutions (increased capital and liquidity requirements for large banks), regulatory deck-chair-shuffling (merging the oversight functions of the OCC and the OTS in a new National Bank Supervisor), or marginally strengthened corporate governance (nonbinding shareholder votes on executive compensation packages).[11] *The New York Times'* Joe Nocera called the Obama plan "little more than an attempt to stick some new regulatory fingers into a very leaky financial dam rather than rebuild the dam itself."[12]

Nonetheless, Wall Street fought tooth and nail to block new regulation and preserve the favorable environment that emerged after the government rescue of 2008–2009, with less competition, a strengthened government guarantee, and no new restrictions on the pursuit of profits. As of October 2009, 1,537 lobbyists representing financial institutions, other businesses, and industry groups had registered to work on financial regulation proposals before Congress—outnumbering by twenty-five to one the lobbyists representing consumer groups, unions, and other supporters of stronger regulation. Even Citigroup, 34 percent owned by the government, hired forty-six lobbyists of its own. In the first nine months of 2009, the industry spent $344 million on lobbying. Senior Obama adviser David Axelrod observed, "You would hope after American taxpayers stepped in to save these companies from a disaster of their own making they would be deploying their army of lobbyists to strengthen and not thwart financial reform," but that was far from the case.[13] Instead, in the words of one congressional staffer, the industry launched "an orchestrated, well-funded effort by the banks to manipulate our legislation and leave no fingerprints."[14]

For example, the regulatory bill introduced in the House Financial Services Committee initially exempted a wide range of derivatives trades by nonfinancial companies from the new requirements proposed by the administration.[15] Michael Greenberger, a veteran of the Commodity Futures Trading Commission, claimed that the draft legislation "had to be written by someone inside the banks, because buried every few pages is a tricky and devilish 'exception.' It would greatly surprise me if these poison pills originated from anyone on Capitol Hill or the Treasury." Journalist William Greider reached the same conclusion after talking to a congressional insider.[16] Although the exemption was subsequently narrowed, this example demonstrates the ability of Wall Street to take advantage of technical complexity to advance its interests.

Wall Street also benefited from the administration's decision to defer actual reform until after the crisis had ebbed—despite Emanuel's "rule one." In part because of the debate over health insurance reform, financial regulation did not receive serious public consideration until fall 2009—after the economy had started growing again, the banking sector had returned to profitability, and months of Republican attacks had reduced Obama's approval ratings and increased skepticism about government action of any kind. By the time battle was joined, both Wall Street and Washington were back to business as usual.

DISMANTLING THE WALL STREET MODEL

For Wall Street's megabanks, business as usual now means inventing tradable, high-margin products; using their market power to capture fees based on trading volume; taking advantage of their privileged market position to place bets in their proprietary trading accounts; and borrowing as much money as possible (in part by engineering their way around capital requirements) to maximize their profits. Before 2008, they benefited from the general expectation that the government would step in if necessary to prevent a catastrophic failure. That expectation did not save Lehman Brothers. But since then, the idea that certain banks are "too big to fail" has virtually become government policy; as a result, they can take on more risk than their competitors, since creditors and counterparties know that the government will clean up after them.

Subprime lending, mortgage-backed securities, collateralized debt obligations (CDOs), and credit default swaps all flowed naturally from this business model, and absent fundamental reform, there is no reason to believe bankers will refrain from inventing new toxic products and precipitating another crisis in the future. What's more, given the growth in the size of the leading banks, the next crisis is likely to be even bigger. As *The Financial Times*' Martin Wolf wrote in September 2009, "What is emerging is a slightly better capitalised financial sector, but one even more concentrated and benefiting from explicit state guarantees. This is not progress: it has to mean still more and bigger crises in the years ahead."[17]

When the next crisis comes, either the government will ride to the rescue once again, costing taxpayers hundreds of billions of dollars, or popular revulsion at bailing out megabanks yet again will prevent Congress and the administration from saving the financial system—with potentially disastrous economic consequences.

The time for change is now. While the crisis was largely wasted in the short term, we have more than a single session of Congress or a single presidential term to fix our financial system. After the Panic of 1907, six years passed before the Federal Reserve was created, and it took another two decades (and the Great Depression) to put the financial system on a sound footing.

Public anger at Wall Street remains high. In an October 2009 poll, only 7 percent of respondents thought that major financial institutions were doing a good job at avoiding another crisis, 75 percent thought that Wall Street would "return to business as usual," 58 percent thought Wall Street had too much influence over government policy, and 59 percent favored more government regulation.[18] But that anger remains diffuse, in part because it is spread across the political spectrum, shared by progressives and conservatives who disagree on the solution. Financial regulation remains a complex topic that many people, including Washington insiders, think should be left to the experts—most of whom were formed on Wall Street or in the Wall Street–friendly climate of the past few decades. Real change will take years, and it will only happen when the conventional wisdom in Washington changes—from the idea that financial innovation and free financial markets are necessarily good, to the idea that concentrated economic and political power can have devastating effects on society.

There are many regulatory policies that could be beneficial, and some of them are included in the various proposals put forward by the Obama administration. But effective reform must address the two basic elements that created the last crisis and, absent change, will create the next one. The first is reckless borrowing and lending, which create a debt bubble that must eventually burst; the second is financial institutions that are so big or systemically important that, when the bubble bursts, they must be bailed out by the government to prevent economic disaster. The first objective should be to protect individual participants in the real economy, both households and businesses, from the potentially abusive behavior of powerful banks. But this is not sufficient to ward off a future crisis, since banks are free to load up on risky assets overseas, out of reach of U.S. protections. Therefore, the second and most important objective must be to protect the economy as a whole from the systemic risk created by enormous banks. Excess optimism, debt bubbles, and overextended banks will likely be with us forever; our goal must be a financial system where those banks can fail without being able to hold up the entire economy.

“RIPPING THE FACE OFF” THE CUSTOMER

Basic microeconomic models assume that the world is made up of rational actors who make accurate decisions, based on perfect information, to maximize their expected utility (benefits to themselves). Given these assumptions, regulation is unnecessary because parties will only engage in transactions that are good for them.

Because lawmakers have long recognized that information available in the market may not be perfect, the consumer protection regime that existed prior to the financial crisis was based on *disclosure*. The Securities Act of 1933 and the Securities Exchange Act of 1934 require companies that sell securities to the public to disclose material information in periodic reports. The Truth in Lending Act of 1968 requires lenders to disclose loan information in standardized form, such as the annual percentage rate, in order to facilitate comparison by borrowers. However, in both cases the legislation does not attempt to determine whether a given financial product is harmful to the consumer; that is left to the market. This is why, for example, there have been no interest rate caps for first mortgages since the Depository Institutions Deregulation and Monetary Control Act of 1980.

The recent financial crisis has exposed the danger of relying on markets to protect consumers. Exotic subprime loans with artificially low initial payments became a vehicle for mortgage brokers to get families into houses they had no realistic hope of affording. While some homebuyers may have consciously used these mortgages to speculate on housing prices, mortgage brokers and lenders also pushed borrowers into unnecessarily high-cost loans. The Center for Responsible Lending found that subprime borrowers ended up paying the equivalent of 1.3 percentage points of interest more for loans obtained through mortgage brokers than they would have paid borrowing directly from a retail lender.[19] The city of Baltimore sued Wells Fargo, alleging that the company systematically targeted minority borrowers through such policies as offering bonuses for steering borrowers who would have qualified for prime loans into subprime loans instead.[20] According to Shaun Donovan, secretary of housing and urban development, 33 percent of subprime mortgages in New York City went to borrowers who could have qualified for conventional loans.[21] These examples demonstrate that unscrupulous brokers and lenders, armed with dense fine print, can induce consumers to choose products that are not in their best interest.

Subprime loans are hardly the only example of the market’s inability to prevent malfeasance. In 2005, the Federal Reserve ruled that overdraft “protection” is not covered by the Truth in Lending Act, allowing banks to charge overdraft fees without their customers’ permission and without disclosing the effective interest rate (although the existence of the programs is typically included in fine-print disclosure statements). In 2009, banks were expected to earn $27 billion in overdraft fees—amounting, on average, to a $34 fee for a $20 transaction.[22] Credit card issuers have also become increasingly adept at maximizing revenues by adopting complex pricing structures that are hard for consumers to understand. For example, universal cross-default provisions (failing to pay one bill to a different company can count as a “default” on your credit card bill) can cause your interest rate to jump up to the “penalty” rate—even retroactively, thanks to two-cycle billing.[23] Universal cross-default and two-cycle billing policies are included in the disclosure statements that card issuers slip into monthly bills, but are often difficult to understand.

Even those who do read the fine print often fail to understand the impact it will have on them individually, due to cognitive biases that lead people to underestimate their usage of credit and the price of credit. For example, 58 percent of people say that they usually pay off their credit cards each month—but only 37–42 percent actually do.[24] The result is that people take on more debt than they intend to and pay a higher price for it than they realize. These errors are by no means confined to low-income, supposedly less sophisticated consumers. The reverse convertibles discussed in chapter 4 were largely sold to relatively affluent investors, for the simple reason that complex financial products have to be sold (few people wake up in the morning suddenly wanting to buy complex structured notes), and larger transactions translate into larger commissions. And the harm caused by deceptive pricing structures goes beyond damage to individual consumers. When it is difficult to assess the likely cost of financial products, even a competitive market does not lead to lower prices for everyone; instead, financial institutions compete by thinking of new tricks to ensnare consumers, and those that refuse to take advantage of their customers lose market share.

Ultimately, simple microeconomic models break down for a few basic reasons. First, innovation leads to financial products that are too complex for even an intelligent, financially savvy person to understand. As former Federal Reserve governor Edward Gramlich wrote of subprime lending, “[I]t is complicated and confusing for borrowers to search out all their available options, to understand all the terms of the loans, and to avoid getting misallocated into a lower credit category than may be appropriate.”[25] Second, people are not rational actors, and financial institutions are more than willing to prey on this weakness. A simple cognitive fallacy such as optimism bias—the tendency to think that you won’t miss a payment on your credit card or overdraw your checking account—causes people to choose financial products that are bad for them. As Shailesh Mehta, former CEO of Providian, said in an interview, “When people make the buying decision, they don’t look at the penalty fees, because they never believe they’ll be late. They never believe they’ll be over limit.”[26] Third, the negotiating table is

tilted in favor of financial services providers, not consumers. Individuals have no ability to negotiate the terms of their mortgages or their credit cards. And the people that they turn to for help with these confusing products, such as mortgage brokers, do not necessarily have their best interests in mind.

These problems were exacerbated by the regulatory structure in place prior to the financial crisis. Enforcement of consumer protection statutes was entrusted to the Federal Reserve, whose priorities have historically been managing the overall economy and ensuring the soundness of bank holding companies. Banks were also subject to various federal bank regulators—the OCC, the OTS, and the Federal Deposit Insurance Corporation—but their primary mission was to prevent banks from failing, not to protect consumers. The patchwork nature of financial regulation, particularly the limited oversight of nonbank lenders, made it possible for financial institutions to engage in their most questionable practices through their least regulated subsidiaries. And with regulators competing for fees from the banks they regulated, consumers' interests were often an afterthought.

The need for stronger consumer protection in the financial arena motivated law professor Elizabeth Warren's 2007 article "Unsafe at Any Rate." Warren began:

> It is impossible to buy a toaster that has a one-in-five chance of bursting into flames and burning down your house. But it is possible to refinance an existing home with a mortgage that has the same one-in-five chance of putting the family out on the street—and the mortgage won't even carry a disclosure of that fact to the homeowner.[27]

Warren called for the creation of a Financial Product Safety Commission, modeled on the Consumer Product Safety Commission, with the power not only to establish disclosure requirements but also to study financial products, review them for safety, and require that dangerous products be modified before being made available to the public.

In 2009, Warren's idea became the Obama administration's proposed Consumer Financial Protection Agency. In its original form, the CFPA would have jurisdiction over almost any financial product sold to individuals, and would have the power to regulate "unfair, deceptive, or abusive acts or practices for all credit, savings, and payment products," including the ability to ban specific practices such as prepayment penalties or yield-spread premiums (the practice of paying mortgage originators higher commissions for generating higher-cost mortgages). The CFPA would also be able to demand that financial service providers offer "plain-vanilla" versions of products, such as a thirty-year fixed rate mortgage, alongside whatever more complicated products they chose, so that consumers could buy a product that they knew was free of hidden traps.[28]

The banking lobby and its defenders closed ranks against the CFPA. Peter Wallison of the American Enterprise Institute claimed that some consumers would be "denied the opportunity to buy products and services that are available to others," restating the textbook assumption that free choice is always good and restrictions on choice are always bad—but neglecting to ask whether meaningful choice exists when it comes to complicated products offered by a handful of oligopolists, such as credit cards.[29] Small community savings banks joined forces with Wall Street, fearful that new regulations would increase their cost of doing business.[30] The incumbent regulators also took a united stand against ceding any authority to a new agency, with Ben Bernanke of the Federal Reserve, John Dugan of the OCC, and Sheila Bair of the FDIC all taking aim at the CFPA before Congress.[31]

The full-court lobbying press had an impact. In September 2009, in order to improve the bill's chances of passage, Barney Frank, the chair of the House Financial Services Committee, eliminated the proposed "plain-vanilla" requirement.[32] (The version of the CFPA proposed in November by Christopher Dodd, chair of the Senate Banking Committee, also left out this requirement.) Small banks also won an exemption in the House from direct examination by the CFPA under most circumstances. But despite the best efforts of the financial sector, the CFPA did emerge intact from the House of Representatives in December 2009. In this case, the Obama administration was willing to confront the banking industry head-on, and Frank was willing to use enough muscle to push it through. The bill introduced by Dodd also includes an independent CFPA, but the sixty-vote threshold in the Senate (to defeat a filibuster) and the apparently unified opposition of the Republican Party's forty-one senators could mean that the banking lobby will still get its way. The large banks' grip on Congress has weakened a little, but perhaps not enough.

By consolidating regulatory authority in an agency that is dedicated to consumer protection, the CFPA would have the potential to deter some of the abusive practices that resulted in families losing their homes and fueled the debt bubble of the 2000s. Even if it does become law, however, the CFPA would still face significant obstacles. At the urging of business groups, both the House and Senate versions of the legislation exempted many businesses that provide credit to their customers, such as auto dealers, and even the administration's original proposal exempted insurance products. These gaps provide opportunities for financial institutions to dodge regulation by redefining their products to fit existing loopholes.

In addition, a consumer protection agency cannot prevent all predatory behavior by financial institutions. The unwitting losers in the financial crisis included many municipalities, pension funds, and other supposedly sophisticated investors who did not understand the products they were buying from their bankers. On the advice of their investment bank, Stifel Nicolaus, five Wisconsin school districts invested $200 million—$165 million of it borrowed from Depfa, an Irish bank—in what they (and their Stifel Nicolaus banker) thought were CDOs. In fact, their $200 million was the collateral for a synthetic CDO,

meaning that the school districts were selling insurance on a portfolio of bonds. When the bonds began defaulting, the school districts ended up losing their $35 million and unable to pay off their loan from Depfa. As financial expert Janet Tavakoli said, "Selling these products to municipalities was pretty widespread. They tend to be less sophisticated. So bankers sell them products stuffed with junk."[33] While businesses, local governments, and institutional investors may not require the same protections as consumers, it is foolish to assume that they will always be able to protect themselves from toxic financial products.

Despite these reservations, a strong, motivated, independent Consumer Financial Protection Agency would serve as a powerful constraint on the ability of financial institutions to take advantage of their customers, discouraging innovations that do not benefit customers and channeling competition into innovations that reduce costs or create new services. The CFPA should also serve as a counterweight within the government to a set of regulatory agencies that have historically seen the world from the perspective of the banks they regulate rather than the customers served by those banks.

However, consumer lending is only one means by which financial institutions can mine the raw material needed for securitization and structured finance. There will always be an unregulated frontier, within our borders or outside them, where banks can place large bets with the potential to go spectacularly badly. A new agency also cannot reverse the political momentum of the last thirty years and dislodge Wall Street from its position of power in Washington. That will require stronger medicine.

TOO BIG TO EXIST

"Too big to fail" was the slogan of the financial crisis. It was the justification for bailing out Fannie Mae, Freddie Mac, AIG, Citigroup, and Bank of America (and, extended into the auto industry, General Motors, Chrysler, and GMAC as well). It was the problem that administration officials and congressmen swore they would fix; even bank CEOs agreed, including Jamie Dimon of JPMorgan Chase, who wrote, "The term 'too big to fail' must be excised from our vocabulary."[34] The phrase has been around at least since the 1984 government rescue of Continental Illinois, and was the subject of a 2004 book by the president and vice president of the Federal Reserve Bank of Minneapolis.[35] But only in 2008 did it become a pillar of government policy.

Most observers of the financial crisis agree on the basic outlines of the "too big to fail" (TBTF) problem. Certain financial institutions are so big, or so interconnected, or otherwise so important to the financial system that they cannot be allowed to go into an uncontrolled bankruptcy; defaulting on their obligations will create significant losses for other financial institutions, at a minimum sowing chaos in the markets and potentially triggering a domino effect that causes the entire system to come crashing down. The bankruptcy of Lehman Brothers in September 2008 accelerated the collapse of American International Group, forcing it into the arms of the Federal Reserve; Lehman's failure also forced the Reserve Primary Fund to "break the buck," causing a sudden loss of confidence in all money market funds; in turn the flood of money out of money market funds caused the commercial paper market to freeze, endangering the ability of many corporations to operate on a day-to-day basis. The failure of Lehman also caused large cash outflows from the remaining stand-alone investment banks, Goldman Sachs and Morgan Stanley. The sequence of falling dominoes was only stopped by massive government rescue measures, and the panic that occurred despite the government's intervention helped transform a mild recession into the most severe recession of the postwar period.

What makes a financial institution too big to fail is the amount of collateral damage that its uncontrolled failure could cause. This damage can take several different forms. If a bank defaults on its debt, other institutions holding its debt will lose money, as happened to the Reserve Primary Fund. Although financial institutions generally attempt to avoid holding too much debt from a single issuer for precisely this reason, the problem is magnified by derivatives. Since credit default swaps allow any company to insure any amount of debt issued by any other company, a bank default can cause losses that exceed its actual debt.

Another problem is that a failing institution could have thousands of open transactions with its counterparties, which are largely other financial institutions. (At the time of its collapse, the face value of AIG's open derivatives contracts was $2.7 trillion—$1 trillion of it with only twelve financial institutions.)[36] For example, a failing bank might have sold credit default swap protection on various securities; its counterparties are assuming that they are perfectly hedged because of those swaps. But when the bank fails, suddenly those hedges vanish, and the counterparties have to take large losses on the underlying securities.* These open transactions can take an almost infinite number of forms; in the modern financial world, any financial institution's position at the end of any given day depends on its counterparties being in business the next day.

Finally, the failure of one bank can cause investors or counterparties to lose confidence in another, similar bank. Because all banks borrow short and lend long, a loss of confidence can kill even a bank that is healthy on paper. After Bear Stearns was sold to JPMorgan Chase in March 2008, all eyes turned to Lehman Brothers; after Lehman failed in September, lack of confidence in Morgan Stanley almost brought it down, and Goldman Sachs was assumed to be next in line.[37] (Merrill Lynch avoided becoming a domino only by selling itself to Bank of America as Lehman collapsed.)

For these reasons, many people have said that the real problem is not the size of a bank (conventionally measured by the total value of its assets), but its interconnectedness.[38] But whatever the term—"too big to fail," "too interconnected to fail," "systemically important" (preferred by Ben Bernanke),[39] "tier 1 financial holding company" (preferred by the Treasury Department)[40]—the fact remains that certain financial institutions cast a sufficiently large shadow over the financial system that they cannot be allowed to fail. As of early 2010, there are at least six banks that are too big to fail—Bank of America, Citigroup, Goldman Sachs, JPMorgan Chase, Morgan Stanley, and Wells Fargo (Figure 7-1)—even leaving aside other institutions such as insurance companies.

Not only is there widespread agreement that several financial institutions are too big to fail, but there is also widespread agreement that this is not good for the financial system or for the economy as a whole. "Too big to fail" creates three major problems for society.

The first problem is that when TBTF institutions do come to the brink of failure, they have to be bailed out, and that usually means they have to be bailed out by the government (and by taxpayers). Even if the government were to decide to wipe out shareholders and replace management, it would still have to bail out the creditors who lent money to the failing bank, since the whole point of the rescue is to limit collateral damage to other financial institutions. A TBTF bank cannot be allowed to go into an ordinary bankruptcy procedure because its creditors and counterparties would be cut off from their money for months, which could be fatal. This means that the government must keep the failing bank afloat and, without a credible threat of bankruptcy to negotiate with, must honor all of the bank's obligations; in other words, the money the bank lost has to be made up with public funds. This was the case with the AIG bailout, where the government eventually committed $180 billion in various rescue packages to keep AIG alive and pay off its counterparties. This need to protect creditors means that even a government takeover (through an FDIC-style conservatorship) will still result in significant losses to taxpayers.

The second problem is that TBTF institutions have a strong incentive to take excess risk, since the government will bail them out in an emergency. All banks are highly leveraged institutions, which means that they are betting with other people's money. There are many strategies available to banks that increase returns for shareholders (and executives) while shifting potential losses onto someone else, such as increasing leverage and holding riskier assets. Ordinarily, creditors should refuse to lend money to a bank that takes on too much risk; but if creditors believe that the government will protect them against losses, they will not play this supervisory function. (This is similar to the decision made by foreign investors in emerging markets: it's always best to lend to the oligarchs, because they are the most likely to be bailed out by the government in a crisis.) There is of course some chance that top executives would lose their jobs in a bailout, but this is more than balanced by the increased upside they gain from taking on more risk. The result is that the largest banks have the most incentive to take risks, and to take risks that would make no economic sense without the government guarantee they get because they are too big to fail. As Larry Summers said in 2000, "It is certain that a healthy financial system cannot be built on the expectation of bailouts."[41]

This problem only gets worse over time. Each time a government bails out its banks, it says, "Never again," hoping to deter the banks from repeating their past sins. But as Piergiorgio Alessandri and Andrew Haldane of the Bank of England argue, this stance becomes less and less credible: "The ex-post costs of crisis mean such a statement lacks credibility. Knowing this, the rational response by market participants is to double their bets. This adds to the cost of future crises. And the larger these costs, the lower the credibility of 'never again' announcements. This is a doom loop."[42]

The third problem is that TBTF banks are bad for competition and therefore bad for the economy. Bond investors realize that megabanks have an implicit government guarantee, and therefore they are willing to lend them money at lower interest rates than their smaller competitors. This is why large banks could pay 0.78 percentage points less for money than small banks in the wake of the financial crisis, giving them a huge competitive advantage. Dean Baker and Travis McArthur calculate that this hidden subsidy was worth up to $34 billion for eighteen large banks in 2009, accounting for roughly half of their profits.[43] This subsidy makes it harder for smaller banks to compete, deterring new entrants and only strengthening the long-term process of consolidation and concentration in the financial sector.
